Abstract

We present a study of $D = 4$ supersymmetric Yang-Mills matrix models with $SO(3)$ mass terms based on the cohomological approach and the Monte Carlo method.

In the bosonic models we show the existence of an exotic first/second order transition from a phase with a well defined background geometry (the fuzzy sphere) to a phase with commuting matrices with no geometry in the sense of Connes. At the transition point the sphere expands abruptly to infinite size then it evaporates as we increase the temperature (the gauge coupling constant). The transition looks first order due to the discontinuity in the action whereas it looks second order due to the divergent peak in the specific heat.

The fuzzy sphere is stable for the supersymmetric models in the sense that the bosonic phase transition is turned into a very slow crossover transition. The transition point is found to scale to zero with N. We conjecture that the transition from the background sphere to the phase of commuting matrices is associated with spontaneous supersymmetry breaking.

The eigenvalues distribution of any of the bosonic matrices in the matrix phase is found to be given by a non-polynomial law obtained from the fact that the joint probability distribution of the four matrices is uniform inside a solid ball with radius R. The eigenvalues of the gauge field on the background geometry are also found to be distributed according to this non-polynomial law.

We also discuss the $D = 3$ models and by using cohomological deformation, localization techniques and the saddle-point method we give a derivation of the $D = 3$ eigenvalues distribution starting from a particular $D = 4$ model.

*An early version of this work titled "Noncommutative Gauge Theory As/Is Matrix Models Around Fuzzy Vacua And Emergent Geometry" was presented to BM Annaba University as a habilitation thesis on 20 january 2011.

1 Introduction

It can be argued using the principles of quantum mechanics and classical general relativity that the picture of spacetime at the very large as being a smooth manifold must necessarily break down at the Planck scale λ_p [1, 2]. At this scale localization looses its operational meaning due to intense gravitational fields and formation of black holes and as a consequence one expects spacetime uncertainty relations which in turn strongly suggest that spacetime has a quantum structure expressed by $[x_\mu, x_\nu] = i\lambda_p^2 Q_{\mu\nu}$. The geometry of spacetime at the very small is therefore noncommutative.

Noncommutative geometry [23], see also [74–78] and [79], allows for the description of the geometry of smooth differentiable manifolds in terms of the underlying C^*-algebra of functions defined on these manifolds. Indeed given the following three data a) the algebra $\mathcal{A} = C^\infty(M)$ of complex valued smooth and continous functions on a manifold M, b) the Hilbert space $\mathcal{H} = L^2(M, S)$ of square integrable sections of the irreducible spinor bundle over M and c) the Dirac operator $\mathcal{D} = \gamma^\mu(\partial_\mu + \frac{1}{2}\omega_{\mu ab}\gamma^a\gamma^b)$ associated with the Levi-Civita connection ω one can reconstruct completely the differential geometry of the manifold M. These three data compose the so-called spectral triple $(\mathcal{A}, \mathcal{H}, \mathcal{D})$ corresponding to the Riemannian manifold M. In the absence of spin structure it is sufficient to use the Laplacian Δ instead of the Dirac operator in the spectral triple.

Noncommutative geometry is also more general than ordinary differential geometry in that it also enables us to describe algebraically the geometry of arbitrary spaces (which a priori do not need to consist of points) in terms of spectral triples. The paradigm of noncommutative geometry adopted so often in physics is to generalize the ordinary commutative space M by replacing the commutative algebra $\mathcal{A}$ by a noncommutative algebra $\mathcal{A}_\theta$. The result of this deformation is in general a noncommutative space M_θ defined precisely by the spectral triple $(\mathcal{A}_\theta, \mathcal{H}_\theta, \mathcal{D}_\theta/\Delta_\theta)$ where the Hilbert space $\mathcal{H}_\theta$ is the representation space of the noncommutative algebra $\mathcal{A}_\theta$ and $\mathcal{D}_\theta/\Delta_\theta$ is the deformation of the commutative Dirac operator/Laplacian $\mathcal{D}/\Delta$ [23, 79].

Noncommutative geometry was also proposed (in fact earlier than renormalization) as a possible way to eliminate ultraviolet divergences in quantum field theories [80, 81]. The quantum spacetime of [1, 2] is Lorentz-covariant based on the commutation relations $[x_\mu, x_\nu] = i\lambda_p^2 Q_{\mu\nu}$ with $Q_{\mu\nu}$ satisfying $[x_\lambda, Q_{\mu\nu}] = 0$, $Q_{\mu\nu}Q^{\mu\nu} = 0$ and $(\frac{1}{2}\epsilon_{\mu\nu\lambda\rho}Q^{\mu\nu}Q^{\lambda\rho})^2 = 1$. As it turns out quantum field theory on this space is ultraviolet finite [82] which is a remarkable consequence of spacetime quantization. This result is however not very surprising. Indeed this phenomena of "regularization by quantization" already happens in quantum mechanics. For example while classical mechanics fail to explain the blackbody radiation in the ultraviolet (the UV catastroph) quantum mechanics reproduces the correct (finite) answer given by the famous experimentally verified Stefan-Boltzman law.

Noncommutative field theory is by definition a field theory based on a noncommutative spacetime [26,27]. The most studied examples in the literature are the Moyal-Weyl spaces $\mathbf{R}^d_\theta$ which correspond to the case $Q_{\mu\nu} = \theta_{\mu\nu}$ where $\theta_{\mu\nu}$ are rank 2 (or 1) antisymmetric constant tensors, i.e.

$$[x_\mu, x_\nu] = i\theta_{\mu\nu}. \tag{1.1}$$

This clearly breakes Lorentz symmetry. The corresponding quantum field theories are not UV finite [125] and furthermore they are plagued with the so-called UV-IR mixing phenomena [83].

For example in the case of scalar field theory on Moyal-Weyl spaces the UV-IR mixing was shown to destroy the perturbative renormalizability of the theory in [109, 110]. The UV-IR mixing in this model means in particular that the non-planar contribution to the two-point function which is finite for generic values of the external momentum behaves as $1/(\theta p)^2$ in the limit $p \longrightarrow 0$ and/or $\theta \longrightarrow 0$. The physics at very large distances is thus altered by the noncommutativity which is supposed to be relevant only at very short distances. Equivalently it was shown in [111] that although the renormalization group equations are finite in the IR regime their perturbative approximations are IR divergent. In [112–114] a modified scalar field theory on noncommutative $\mathbf{R}^d_\theta$ was proposed and shown to be renormalizable to all orders in perturbation theory in $d = 2$ and 4. The modification consists of making the action invariant under the duality transformation of [115] by adding a harmonic oscillator potential to the kinetic term which precisely modifies the free theory as desired.

For scalar field theory with ϕ^4 interaction the phase diagram consists of three phases instead of the usual two phases found in commutative scalar field theory. We observe a disordered phase, a uniform ordered phase and a novel nonuniform ordered phase which meet at a triple point possibly a Lifshitz point [116, 117]. The nonuniform phase is the analogue of the matrix phase in pure gauge models (see below) in the sense that in this phase the spacetime metric is modified by quantum fluctuations of the noncommutative field theory since the Laplacian at the transition point is found to be $(\partial^2_\mu)^2$ and not ∂^2_μ [116]. In the nonuniform ordered phase we have spontaneous breakdown of translational invariance [117–119]. The transition from the disordered phase to the nonuniform ordered phase is thought to be first order and the nonuniform ordered phase is a periodically modulated phase which for small values of the coupling constant is dominated by stripes [117]. This should hold even in two dimensions.

This behavior was confirmed in Monte Carlo simulations on the noncommutative torus [40–42] in [120, 121] and on the fuzzy sphere [29, 30] in [122–124].

It is therefore natural to conjecture that there must exist two fixed points in this theory, the usual Wilson-Fisher fixed point at $\theta = 0$ and a novel fixed point at $\theta = \infty$ which is intimately related to the underlying matrix model structure of the model [126]. The crucial input in a scalar field theory on a noncommutative space is the scalar potential which when written in the matrix base is a random matrix theory which for a ϕ^4 interaction is given by

$$V = N(aTrM^2 + bTrM^4). \tag{1.2}$$

The main property of this matrix model which plays a central role in the phase structure of a noncommutative ϕ^4 interaction is the existence of one-cut/two-cut transition, with the one-cut (disordered) phase corresponding to $a \geq a_*$ where [132, 133]

$$a_* = -2\sqrt{b}. \tag{1.3}$$

The kinetic term is trying to add a geometry to the dynamics of the matrix M which is at the heart of the rich phase structure we observe. For small b the usual Ising model transition is expected and the $\theta = 0$ fixed point should control the physics. We expect on the other hand that the $\theta = \infty$ fixed point should control most of the phase diagram since generically the ϕ^4 interaction, i.e. the coupling b is not weak.

Noncommutative gauge theories attracted a lot of interest in recent years because of their appearance in string theory [12, 84, 85]. For example it was discovered that the dynamics of open strings moving in a flat space in the presence of a non-vanishing Neveu-Schwarz B-field and with Dp-branes is equivalent to leading order in the string tension to a gauge theory on a Moyal-Weyl space $\mathbf{R}^d_\theta$. Extension of this result to curved spaces is also possible at least in one particular instance, namely the case of open strings moving in a curved space with $\mathbf{S}^3$ metric. The resulting effective gauge theory lives on a noncommutative fuzzy sphere $\mathbf{S}^2_N$ [86–88].

Another class of noncommutative spaces, besides Moyal-Weyl spaces, which will be very important for us in this article is fuzzy spaces [89, 90]. Fuzzy physics is by definition a field theory based on fuzzy spaces [91, 92]. The original idea of discretization by quantization (fuzzification) works well for co-adjoint orbits such as projective spaces. A seminal example of fuzzy spaces is the fuzzy two-dimensional sphere $\mathbf{S}^2_N$ [29, 30]. The fuzzy sphere is defined by three $N \times N$ matrices x_i, $i = 1, 2, 3$ playing the role of coordinates operators satisfying $\sum_i x_i^2 = 1$ and the commutation relations

$$[x_i, x_j] = i\theta\epsilon_{ijk}x_k \ , \ \theta = \frac{1}{\sqrt{c_2}} \ , \ c_2 = \frac{N^2 - 1}{4}. \tag{1.4}$$

The fuzzy sphere which is the simplest among fuzzy projective spaces was actually proposed as a nonperturbative regularization of ordinary quantum field theory in [127]. See also [98, 101, 102, 128]. However we know now that this can not be correct because of the complicated phase structure of noncommutative ϕ^4 scalar field theories on the fuzzy sphere [129, 130]. Instead it is becoming very clear that it is more appropriate to think of the fuzzy sphere as a nonperturbative regularization of noncommutative quantum field theory on Moyal-Weyl plane. For example we can show in a particular double scaling limit that the nonperturbative phase structure of scalar fields on the Moyal-Weyl plane can be rigorously identified with the nonperturbative phase structure of scalar fields on the fuzzy sphere, and in particular the matrix or nonuniform ordered phase on the fuzzy sphere goes precisely to the stripe phase on the Moyal-Weyl plane [131].

In 3−dimensions we have the fuzzy three sphere $\mathbf{S}^3_N$ [93]. In 4−dimensions we have 3 fuzzy manifolds which are obtained from co-adjoint orbits. The direct product of fuzzy two spheres $\mathbf{S}^2_N \times \mathbf{S}^2_N$ [94], fuzzy $\mathbf{CP}^2_N$ [95, 96] and fuzzy $\mathbf{S}^4_N$ as a squashed fuzzy $\mathbf{CP}^3_N$ [97].

The most appealing aspect of discretization by quantization remains its remarkable success in preserving continuous symmetries including supersymmetry and capturing correctly topological properties [31, 91, 92]. Indeed the fuzzy approach does not suffer from fermion doubling [98–100], it extends naturally to supersymmetry [101–104] and it captures correctly nontrivial field configurations such as monopoles and instantons using the language of projective modules and K-theory [105–108].

The noncommutative Moyal-Weyl spaces should be thought of as infinite dimensional matrix algebras not as continuum manifolds. Quantum fluctuations of a gauge theory on $\mathbf{R}^d_\theta$ will generically make the vacuum which is here the Moyal-Weyl space itself unstable. To see this effect we formally rewrite gauge theory on $\mathbf{R}^d_\theta$ as a matrix model with $N-$dimensional matrices $\hat{D}_i$ where $N \longrightarrow \infty$. This is given by

$$S = \frac{\sqrt{\det(\pi\theta B)}}{2g^2} Tr_{\mathcal{H}} \left(i[\hat{D}_i, \hat{D}_j] - \frac{1}{\theta} B^{-1}_{ij} \right)^2 . \tag{1.5}$$

By computing the effective potential in the configuration $\hat{D}_i = -\phi B^{-1}_{ij} \hat{x}_j$ we will verify explicitly that the Moyal-Weyl space itself, i.e the algebra $[x_\mu, x_\nu] = i\theta_{\mu\nu}$, ceases to exist above a certain value g_* of the gauge coupling constant. We find $g^2_* = \pi^2/N$ in four dimensions (see section 2). In other words by moving in the phase diagram from strong coupling to weak coupling the geometry of the Moyal-Weyl spaces (including the star product and the representation of operators by fields) emerges at the critical point g_*. As a consequence a natural regularization of Moyal-Weyl spaces must include in a fundamental way matrix degrees of freedom. The regularization which will be employed in this article is given by fuzzy projective spaces [134]. The main reason behind this choice is the fact that the phenomena of emergent geometry [20,135,136] which we observed here on Moyal-Weyl spaces shows up also in all matrix models on fuzzy projective spaces.

Let us note the deep connection which exists between the geometry in transition we observe here on Moyal-Weyl space $\mathbf{R}^4_\theta$ and the perturbative UV-IR mixing and beta function of $U(1)$ gauge theory computed in [137,138]. The structure of the effective potential in 2 dimensions indicates that there is no transition and no UV-IR mixing in $U(1)$ gauge theory on $\mathbf{R}^2_\theta$ and therefore the theory is expected to be renormalizable. This was shown numerically to be true in [139]. We also expect that noncommutative $\mathcal{N} = 1$ supersymmetric $U(1)$ gauge theory in 4 dimensions is renormalizable.

Let us note also that fuzzy regularization is different from the usual one which is based on the Eguchi-Kawai model [13] and the noncommutative torus [40–42], i.e the twisted Eguchi-Kawai model. The twisted Eguchi-Kawai model was employed as a nonperturbative regularization of noncommutative gauge theory in [140–142] where the instability and the phase transition discussed here were also obtained.

Finally we note that the strong coupling phase (above g_*) of noncommutative gauge theory on $\mathbf{R}^d_\theta$ corresponds to $\theta = \infty$. It is dominated by commuting operators. The limit $\theta \longrightarrow \infty$ is the planar theory (only planar graphs survive) [125] and it is intimately related to large N limits of hermitian matrix models [143,144] and [117]. In this phase of commuting operators supersymmetry may be broken.

The phenomena of emergent geometry associated with noncommutative gauge theory is therefore a major motivation behind choosing fuzzy projective spaces as a nonperturbative regularization of Moyal-Weyl spaces. The other motivation comes of course from the novel phase known variously as stripe, nonuniform ordered or matrix phase found in noncommutative scalar field theory which we have only briefly discussed in this introduction. The phenomena of emergent geometry is also, on the other hand, intimately tied to reduced Yang-Mills models which will be the topic of central interest in the remainder of this introduction and in most of this article.

It is well established that reduced Yang-Mills theories play a central role in the non-perturbative definitions of M-theory and superstrings. The BFSS conjecture [3] relates discrete light-cone quantization (DLCQ) of $M-$theory to the theory of N coincident $D0$ branes which at low energy (small velocities and/or string coupling) is the reduction to $0+1$ dimension of the 10 dimensional $U(N)$ supersymmetric Yang-Mills gauge theory [4]. The BFSS model is therefore a Yang-Mills quantum mechanics which is supposed to be the UV completion of 11 dimensional supergravity. As it turns out the BFSS action is nothing else but the regularization of the supermembrane action in the light cone gauge [5].

The BMN model [6] is a generalization of the BFSS model to curved backgrounds. It is obtained by adding to the BFSS action a one-parameter mass deformation corresponding to the maximally supersymmetric pp-wave background of 11 dimensional supergravity. See for example [7–9]. We note, in passing, that all maximally supersymmetric pp-wave geometries can arise as Penrose limits of $AdS_p \times S^q$ spaces [10].

The IKKT model [11] is, on the other hand, a Yang-Mills matrix model obtained by dimensionally reducing 10 dimensional $U(N)$ supersymmetric Yang-Mills gauge theory to $0+0$ dimensions. The IKKT model is postulated to provide a constructive definition of type II B superstring theory and for this reason it is also called type IIB matrix model. Supersymmetric analogue of the IKKT model also exists in dimensions $d = 3, 4$ and 6 while the partition functions converge only in dimensions $d = 4, 6$ [52, 53].

The IKKT Yang-Mills matrix models can be thought of as continuum Eguchi-Kawai reduced models as opposed to the usual lattice Eguchi-Kawai reduced model formulated in [13]. We point out here the similarity between the conjecture that the lattice Eguchi-Kawai reduced model allows us to recover the full gauge theory in the large N theory and the conjecture that the IKKT matrix model allows us to recover type II B superstring.

The relation between the BFSS Yang-Mills quantum mechanics and the IKKT Yang-Mills matrix model is discussed at length in the seminal paper [12] where it is also shown that toroidal compactification of the D-instanton action (the bosonic part of the IKKT action) yields, in a very natural way, a noncommutative Yang-Mills theory on a dual noncommutative torus [24]. From the other hand, we can easily check that the ground state of the D-instanton action is given by commuting matrices which can be diagonalized simultaneously with the eigenvalues giving the coordinates of the D-branes. Thus at tree-level an ordinary spacetime emerges from the bosonic truncation of the IKKT action while higher order quantum corrections will define a noncommutative spacetime.

In summary, Yang-Mills matrix models which provide a constructive definition of string theories will naturally lead to emergent geometry [20] and non-commutative gauge theory [145, 146]. Furthermore, non-commutative geometry [23, 76] and their non-commutative field theories [26,27] play an essential role in the non-perturbative dynamics of superstrings and M-theory. Thus the connections between non-commutative field theories, emergent geometry and matrix models from one side and string theory from the other side run deep.

It seems therefore natural that Yang-Mills matrix models provide a non-perturbative framework for emergent spacetime geometry and non-commutative gauge theories. Since non-commutativity is the only extension which preserves maximal supersymmetry, we also hope that Yang-Mills matrix models will provide a regularization which preserves

supersymmetry [28].

In this article we will explore in particular the possibility of using IKKT Yang-Mills matrix models in dimensions 4 and 3 to provide a non-perturbative definition of emergent spacetime geometry, non-commutative gauge theory and supersymmetry in two dimensions. From our perspective in this article, the phase of commuting matrices has no geometry in the sense of Connes and thus we need to modify the models so that a geometry with a well defined spectral triple can also emerge alongside the phase of commuting matrices.

There are two solutions to this problem. The first solution is given by adding mass deformations which preserve supersymmetry to the flat IKKT Yang-Mills matrix models [14] or alternatively by an Eguchi-Kawai reduction of the mass deformed BFSS Yang-Mills quantum mechanics constructed in [15, 64–66]. The second solution, which we have also considered in this article, is given by deforming the flat Yang-Mills matrix model in $D = 4$ using the powerful formalism of cohomological Yang-Mills theory [32–34, 68].

These mass deformed or cohomologically deformed IKKT Yang-Mills matrix models are the analogue of the BMN model and they typically include a Myers term [16] and thus they will sustain the geometry of the fuzzy sphere [29, 30] as a ground state which at large N will approach the geometry of the ordinary sphere, the ordinary plane or the non-commutative plane depending on the scaling limit. Thus a non-perturbative formulation of non-commutative gauge theory in two dimensions can be captured rigorously within these models [19, 147, 148]. See also [70, 71].

This can in principle be generalized to other fuzzy spaces [31] and higher dimensional non-commutative gauge theories by considering appropriate mass deformations of the flat IKKT Yang-Mills matrix models.

The problem or virtue of this construction, depending on the perspective, is that in these Yang-Mills matrix models the geometry of the fuzzy sphere collapses under quantum fluctuations into the phase of commuting matrices. Equivalently, it is seen that the geometry of the fuzzy sphere emerges from the dynamics of a random matrix theory [56, 58]. Supersymmetry is naturally expected to stabilize the spacetime geometry, and in fact the non stability of the non-supersymmetric vacuum should have come as no surprise to us [35].

We should mention here the approach of [38] in which a noncommutative Yang-Mills gauge theory on the fuzzy sphere emerges also from the dynamics of a random matrix theory. The fuzzy sphere is stable in the sense that the transition to commuting matrices is pushed towards infinite gauge coupling at large N [57]. This was achieved by considering a very special non-supersymmetric mass deformation which is quartic in the bosonic matrices. This construction was extended to a noncommutative gauge theory on the fuzzy sphere based on co-adjoint orbits in [39].

Let us also note here that the instability and the phase transition discussed here were also observed on the non-commutative torus in [72, 73, 140–142] where the twisted Eguchi-Kawai model was employed as a non-perturbative regularization of non-commutative Yang-Mills gauge theory [40–42].

In this article we will study, using cohomological matrix theory and the Monte Carlo

method, the mass deformed Yang-Mills matrix model in $D = 4$ as well as a particular truncation to $D = 3$. We will derive and study a one-parameter cohomological deformation of the Yang-Mills matrix model which coincides with the mass deformed model in $D = 4$ when the parameter is tuned appropriately. We will show that the first/second order phase transition from the fuzzy sphere to the phase of commuting matrices observed in the bosonic models is converted in the supersymmetric models into a very slow crossover transition with an arbitrary small transition point in the large N limit. We will determine the eigenvalues distributions for both $D = 4$ and $D = 3$ throughout the phase diagram. The $D = 3$ eigenvalues distribution can be obtained from a particular $D = 4$ model by means of the methods of cohomological Yang-Mills matrix theory, large N saddle point and localization techniques [36, 37].

This article is organized as follows: In section 2 we give a brief discussion of the phenomena of emergent geometry on the Moyal-Weyl space using the effective potential. In section 3 we give a short review on fuzzy projective spaces. In section 4 we review results on emergent geometry in bosonic $D = 3$ Yang-Mills matrix models. In section 5 we will derive the mass deformed Yang-Mills quantum mechanics from the requirement of supersymmetry and then reduce it further to obtain Yang-Mills matrix model in $D = 4$ dimensions. In section 6 we will derive a one-parameter family of cohomologically deformed models and then show that the mass deformed model constructed in section 5 can be obtained for a particular value of the parameter. In section 7 we report our first Monte Carlo results for the model $D = 4$ including the eigenvalues distributions and also comment on the $D = 3$ model obtained by simply setting the fourth matrix to 0. In section 8 we solve a particular $D = 4$ model and show by means of cohomological Yang-Mills matrix theory and localization techniques that it is equivalent to the matrix $D = 3$ Chern-Simons theory. By using the saddle point method we derive the $D = 3$ eigenvalues distribution. We conclude in section 9 with a comprehensive summary of the results and discuss future directions. The detail of the simulations are found in appendices A and B while appendix C contains a detail calculation of the supersymmetric mass deformation and appendix D contains a calculation of the star product on the Moyal-Weyl plane starting from the star product on the fuzzy sphere.

2 Gauge Theory on Noncommutative Moyal-Weyl Spaces

The basic noncommutative gauge theory action of interest to us in this article can be obtained from a matrix model of the form (see [26] and references therein)

$$S = \frac{\sqrt{\theta^d \det(\pi B)}}{2g^2} Tr_{\mathcal{H}} \hat{F}_{ij}^2 = \frac{\sqrt{\theta^d \det(\pi B)}}{2g^2} Tr_{\mathcal{H}} \left(i[\hat{D}_i, \hat{D}_j] - \frac{1}{\theta} B_{ij}^{-1} \right)^2 . \tag{2.1}$$

Here $i, j = 1, ..., d$ with d even and θ has dimension of length squared so that the connection operators $\hat{D}_i$ have dimension of $(\text{length})^{-1}$. The coupling constant g is of dimension $(\text{mass})^{2-\frac{\mathrm{d}}{2}}$ and B^{-1} is an invertible tensor which in 2 dimensions is given by $B_{ij}^{-1} = \epsilon_{ij}^{-1} =$

$-\epsilon_{ij}$ while in higher dimensions is given by

$$B^{-1}_{ij} = \begin{pmatrix} -\epsilon_{ij} & & & \\ & . & & \\ & & . & \\ & & & -\epsilon_{ij} \end{pmatrix}. \tag{2.2}$$

The operators $\hat{A}_i$ belong to an algebra $\mathcal{A}$. The trace is taken over some infinite dimensional Hilbert space $\mathcal{H}$ and hence $Tr_{\mathcal{H}}[\hat{D}_i, \hat{D}_j]$ is $\neq 0$ in general, i.e. $Tr_{\mathcal{H}}[\hat{D}_i, \hat{D}_j]$ is in fact a topological term [12]. Furthermore we will assume Euclidean signature throughout.

Minima of the model (2.1) are connection operators $\hat{D}_i = \hat{B}_i$ satisfying

$$i[\hat{B}_i, \hat{B}_j] = \frac{1}{\theta} B^{-1}_{ij}. \tag{2.3}$$

We view the algebra $\mathcal{A}$ as $\mathcal{A} = \mathrm{Mat}_n(\mathbf{C}) \otimes \mathcal{A}_n$. The trace $Tr_{\mathcal{H}}$ takes the form $Tr_{\mathcal{H}} = Tr_n Tr_{\mathcal{H}_n}$ where $\mathcal{H}_n$ is the Hilbert space associated with the elements of $\mathcal{A}_n$. The configurations $\hat{D}_i = \hat{B}_i$ which solve equation (2.3) can be written as

$$\hat{B}_i = -\frac{1}{\theta} B^{-1}_{ij} \hat{x}_j \otimes \mathbf{1}_n. \tag{2.4}$$

The operators $\hat{x}_i$ which are elements of $\mathcal{A}_n$ can be identified with the coordinate operators on the noncommutative Moyal-Weyl space $\mathbf{R}^d_\theta$ with the usual commutation relation

$$[\hat{x}_i, \hat{x}_j] = i\theta B_{ij}. \tag{2.5}$$

Derivations on $\mathbf{R}^d_\theta$ are defined by

$$\hat{\partial}_i = i\hat{B}_i. \tag{2.6}$$

Indeed we compute

$$[\hat{\partial}_i, \hat{x}_j] = \delta_{ij}. \tag{2.7}$$

The sector of this matrix theory which corresponds to a noncommutative $U(n)$ gauge field on $\mathbf{R}^d_\theta$ is therefore obtained by expanding $\hat{D}_i$ around $\hat{B}_i \otimes \mathbf{1}_n$. We write the configurations

$$\hat{D}_i = -\frac{1}{\theta} B^{-1}_{ij} \hat{x}_j \otimes \mathbf{1}_n + \hat{A}_i, \;\; \hat{A}^+_i = \hat{A}_i. \tag{2.8}$$

The operators $\hat{A}_i$ are identified with the components of the dynamical $U(n)$ noncommutative gauge field. The corresponding $U(n)$ gauge transformations which leave the action (2.1) invariant are implemented by unitary operators $U = \exp(i\Lambda)$, $UU^+ = U^+U = 1$, $\Lambda^+ = \Lambda$ which act on the Hilbert space $\mathcal{H} = \mathcal{H}_n \oplus ... \oplus \mathcal{H}_n$ as $\hat{D}_i \longrightarrow U\hat{D}_iU^+$, i.e. $\hat{A}_i \longrightarrow U\hat{A}_iU^+ - iU[\hat{\partial}_i, U^+]$ and $\hat{F}_{ij} \longrightarrow U\hat{F}_{ij}U^+$. In other words $U(n)$ in this setting must be identified with $U(\mathcal{H}_n \oplus ... \oplus \mathcal{H}_n)$. The action (2.1) can be put into the form

$$S = \frac{\sqrt{\theta^d \det(\pi B)}}{4g^2} Tr_{\mathcal{H}_n}(\hat{F}^C_{ij})^2. \tag{2.9}$$

The curvature $\hat{F}_{ij}^C$ where C is a $U(n)$ index which runs from 1 to n^2 is given by

$$\hat{F}_{ij}^C = [\hat{\partial}_i, \hat{A}_j^C] - [\hat{\partial}_j, \hat{A}_i^C] - \frac{1}{2} f_{ABC}\{\hat{A}_i^A, \hat{A}_j^B\} + \frac{i}{2} d_{ABC}[\hat{A}_i^A, \hat{A}_j^B]. \tag{2.10}$$

In calculating $\hat{F}_{ij}^C$ we used $[T_A, T_B] = i f_{ABC} T_C$, $\{T_A, T_B\} = d_{ABC} T_c$ and $Tr T_A T_B = \frac{\delta_{AB}}{2}$. More explicitely we have defined $T_a = \frac{\lambda_a}{2}$ for the $SU(n)$ part and $T_0 = \frac{1}{\sqrt{2n}} \mathbf{1}_n$ for the $U(1)$ part. The symbols d_{ABC} are defined such that d_{abc} are the usual $SU(n)$ symmetric symbols while $d_{ab0} = d_{a0b} = d_{0ab} = \sqrt{\frac{2}{n}}\delta_{ab}$, $d_{a00} = 0$ and $d_{000} = \sqrt{\frac{2}{n}}$.

Finally it is not difficult to show using the Weyl map, viz the map between operators and fields, that the matrix action (2.9) is precisely the usual noncommutative $U(n)$ gauge action on $\mathbf{R}_\theta^d$ with a star product $*$ defined by the parameter θB_{ij} [26, 27]. In particular the trace $Tr_{\mathcal{H}_n}$ on the Hilbert space $\mathcal{H}_n$ can be shown to be equal to the integral over spacetime. We get

$$S = \frac{1}{4g^2} \int d^d x \ (F_{ij}^C)^2 \ , \ F_{ij}^C = \partial_i A_j^C - \partial_j A_i^C - \frac{1}{2} f_{ABC}\{A_i^A, A_j^B\}_* + \frac{i}{2} d_{ABC}[A_i^A, A_j^B]_*. \tag{2.11}$$

Let us note that although the dimensions $\dim\mathcal{H}$ and $\dim\mathcal{H}_n$ of the Hilbert spaces $\mathcal{H}$ and $\mathcal{H}_n$ are infinite the ratio $\dim\mathcal{H}/\dim\mathcal{H}_n$ is finite equal n. The number of independent unitary transformations which leave the configuration (2.4) invariant is equal to $\dim\mathcal{H} - \dim\mathcal{H}_n - n^2$. This is clearly less than $\dim\mathcal{H}$ for any $n \geq 2$. In other words from entropy counting the $U(1)$ gauge group (i.e. $n = 1$) is more stable than all higher gauge groups. As we will show the $U(1)$ gauge group is in fact energetically favorable in most of the finite N matrix models which are proposed as non-perturbative regularizations of (2.1) in this article. Stabilizing $U(n)$ gauge groups requires adding potential terms to the action. In the rest of this section we will thus consider only the $U(1)$ case for simplicity.

Quantization of the matrix model (2.1) consists usually in quantizing the model (2.11). As we will argue shortly this makes sense only for small values of the coupling constant g^2 which are less than a critical value g_*^2. Above g_*^2 the configuration $\hat{B}_i$ given by (2.4) ceases to exist, i.e. it ceases to be the true minimum of the theory and as a consequence the expansion (2.8) does not make sense.

In order to compute this transition we use the one-loop effective action which can be easily obtained in the Feynamn-'t Hooft background field gauge. We find the result

$$\Gamma = S + \frac{1}{2} Tr_d Tr_{\text{ad}} \ln\left(\mathcal{D}^2 \delta_{ij} - 2i\mathcal{F}_{ij}\right) - Tr_{\text{ad}} \ln \mathcal{D}^2. \tag{2.12}$$

The operators $\mathcal{D}^2 = \mathcal{D}_i \mathcal{D}_i$, $\mathcal{D}_i$ and $\mathcal{F}_{ij}$ act by commutators, viz $\mathcal{D}^2(..) = [\hat{D}_i, [\hat{D}_i, ..]]$, $\mathcal{D}_i(..) = [\hat{D}_i, ..]$ and $\mathcal{F}_{ij}(..) = [\hat{F}_{ij}, ..]$. Next we compute the effective potential in the configuration $\hat{D}_i = -\phi B_{ij}^{-1} \hat{x}_j$. The curvature $\hat{F}_{ij}$ in this configuration is given by $\theta \hat{F}_{ij} = (\theta^2\phi^2 - 1) B_{ij}^{-1}$. The trace over the Hilbert space $\mathcal{H}$ is regularized such that $Tr_{\mathcal{H}} \mathbf{1} = N$ is a very large but finite natural number. We will also need $\sum_{i,j} B_{ij}^{-1} B_{ij}^{-1} = d$. The effective potential for $d \neq 2$ is given by

$$\frac{V}{(d-2)N^2} = \alpha(\theta^2\phi^2 - 1)^2 + \ln\phi. \tag{2.13}$$

The coupling constant α is given by

$$\alpha = \frac{d}{d-2}\frac{\pi^{\frac{d}{2}}}{2}\frac{1}{\lambda^2 N}\ ,\ \lambda = \theta^{1-\frac{d}{4}}g. \tag{2.14}$$

We take the limit $N \longrightarrow \infty$ keeping $\lambda^2 N$ fixed. It is not difficult to show that the minimum of the above potential is then given by

$$(\theta\phi)^2 = \frac{1+\sqrt{1-\frac{1}{\alpha}}}{2}. \tag{2.15}$$

The critical values are therefore given by

$$\alpha_* = 1 \Leftrightarrow \lambda_*^2 N = \frac{d}{d-2}\frac{\pi^{\frac{d}{2}}}{2}. \tag{2.16}$$

Thus the configuration $\hat{D}_i = -\phi B_{ij}^{-1}\hat{x}_j$ exists only for values of the coupling constant λ which are less than λ_*. Above λ_* true minima of the model are given by commuting operators,i.e.

$$i[\hat{B}_i, \hat{B}_j] = 0. \tag{2.17}$$

By comparing with (2.3) we see that this phase corresponds to $\theta = \infty$. The limit $\theta \longrightarrow \infty$ is the planar theory (only planar graphs survive) [125] which is intimately related to large N limits of hermitian matrix models [117].

This transition from the noncommutative Moyal-Weyl space (2.3) to the commuting operators (2.17) is believed to be intimately related to the perturbative UV-IR mixing [83]. Indeed this is true in two dimensions using our formalism here.

In two dimensions we can see that the logarithmic correction to the potential is absent and as a consequence the transition to commuting operators will be absent. The perturbative UV-IR mixing is, on the other hand, absent in two dimensions. Indeed in two dimensions the first nonzero correction to the classical action S in the effective action (2.12) is given by

$$\begin{aligned}
\Gamma &= S - Tr_{\rm ad}\frac{1}{\mathcal{D}^2}\mathcal{F}_{ij}\frac{1}{\mathcal{D}^2}\mathcal{F}_{ij} + ... \\
&= S + (\theta\pi)^2\int_k \frac{1}{k^2}\int_p \frac{1}{p^2}\ Tr_{\mathcal{H}}F_{ij}[e^{ip\hat{x}}, e^{-ik\hat{x}}]\ Tr_{\mathcal{H}}F_{ij}[e^{ik\hat{x}}, e^{-ip\hat{x}}] \\
&= S + 2\int_p Tr|\tilde{F}_{ij}(p)|^2\int_k \frac{1}{k^2}\frac{1}{(p-k)^2}(1-\cos\theta_{ij}p_i k_j)|.
\end{aligned} \tag{2.18}$$

By including a small mass m^2 and using Feynman parameters the planar and non-planar contributions are given respectively by

$$\Pi^{\rm P} = \int_k \frac{1}{k^2+m^2}\frac{1}{(p-k)^2+m^2} = \frac{(\theta_{ij}p_i)^2}{4\pi}\int_0^1 \frac{dx}{z^2}. \tag{2.19}$$

$$\Pi^{\rm NP} = \int_k \frac{1}{k^2+m^2}\frac{1}{(p-k)^2+m^2}\cos\theta_{ij}p_i k_j = \frac{(\theta_{ij}p_i)^2}{4\pi}\int_0^1 \frac{dx}{z^2}zK_1(z). \tag{2.20}$$

In above z is defined by $z^2 = (\theta_{ij}p_i)^2(m^2 + x(1-x)p^2)$ and $K_1(z)$ is the modified Bessel function given by

$$zK_1(z) = \int_0^\infty dt\ e^{-t}\ e^{-\frac{z^2}{4t}} = 1 + \frac{z^2}{2}\ln\frac{ze^c}{2} + ... \tag{2.21}$$

We observe that in two dimensions both the planar and non-planar functions are UV finite, i.e. renormalization of the vacuum polarization is not required. The infrared divergence seen when $m^2 \longrightarrow 0$ cancel in the difference $\Pi^{\rm P} - \Pi^{\rm NP}$. Furthermore $\Pi^{\rm P} - \Pi^{\rm NP}$ vanishes identically in the limit $\theta \longrightarrow 0$ or $p \longrightarrow 0$. In other words there is no UV-IR mixing in the vacuum polarization in two dimensions.

The situation in four dimensions is more involved [137,138]. Explicitly we find that the planar contribution to the vacuum polarization is UV divergent as in the commutative theory, i.e. it is logarithmically divergent and thus it requires a renormalization. It is found that the UV divergences in the $2-$, $3-$ and $4-$point functions at one-loop can be subtracted by a single counter term and hence the theory is renormalizable at this order. The beta function of the theory at one-loop is identical to the beta function of the ordinary pure $SU(2)$ gauge theory. The non-planar contribution to the vacuum polarization at one-loop is UV finite because of the noncommutativity and only it becomes singular in the limit of vanishing noncommutativity and/or vanishing external momentum. This also means that the renormalized vacuum polarization diverges in the infrared limit $p\longrightarrow 0$ and/or $\theta \longrightarrow 0$ which is the definition of the UV-IR mixing.

We expect that supersymmetry will make the Moyal-Weyl geometry and as a consequence the noncommutative gauge theory more stable. In order to see this effect let λ_a, $a = 1, ..., M$ be M massless Majorana fermions in the adjoint representation of the gauge group $U(\mathcal{H})$. We consider the modification of the action (2.1) given by

$$S \longrightarrow S^{'} = S + \frac{\sqrt{\theta^d \det(\pi B)}}{4g^2}\sum_{a=1}^{M} Tr_{\mathcal{H}}\bar{\lambda}_a\gamma_i[\hat{D}_i, \lambda_a]. \tag{2.22}$$

The irreducible representation of the Clifford algebra in d dimensions is $s = 2^{\frac{d}{2}}$ dimensional. Let us remark that in the limit $\theta \longrightarrow 0$ the modified action $S^{'}$ has the same limit as the original action S. By integrating over λ_a in the path integral we obtain the Pfaffian $\big({\rm pf}(\gamma_i\mathcal{D}_i)\big)^M$. We will assume that ${\rm pf}(\gamma_i\mathcal{D}_i) = \big(\det(\gamma_i\mathcal{D}_i)\big)^{\frac{1}{2}}$. The modification of the effective action (2.12) is given by

$$\Gamma \longrightarrow \Gamma^{'} = \Gamma - \frac{M}{4}Tr_s Tr_{\rm ad}\ln\left(\mathcal{D}^2 - \frac{i}{2}\gamma_i\gamma_j\mathcal{F}_{ij}\right). \tag{2.23}$$

It is not very difficult to check that the coefficient of the logarithmic term in the effective potential is positive definite for all M such that $Ms < 2d - 4$. For $Ms = 2d - 4$ the logarithmic term vanishes identically and thus the background (2.4) is completely stable at one-loop order. In this case the noncommutative gauge theory (i.e. the star product representation) makes sense at least at one-loop order for all values of the gauge coupling constant g. The case $Ms = 2d - 4$ in $d = 4$ (i.e. $M = 1$) corresponds to noncommutative

$\mathcal{N}=1$ supersymmetric $U(1)$ gauge theory. In this case the effective action is given by

$$\Gamma^{'} = S + \frac{1}{2}Tr_d Tr_{\rm ad} \ln\Big(\delta_{ij} - 2i\frac{1}{\mathcal{D}^2}\mathcal{F}_{ij}\Big) - \frac{M}{4}Tr_s Tr_{\rm ad}\ln\Big(1 - \frac{i}{2}\gamma_i\gamma_j\frac{1}{\mathcal{D}^2}\mathcal{F}_{ij}\Big). \quad (2.24)$$

This is manifestly gauge invariant. In 4 dimensions we use the identity $Tr_s\gamma_i\gamma_j\gamma_k\gamma_l = s\big(\delta_{ij}\delta_{kl} - \delta_{ik}\delta_{jl} + \delta_{il}\delta_{jk}\big)$ and the first nonzero correction to the classical action S is given by the equation

$$\begin{aligned}\Gamma^{'} &= S + \big(\frac{d-2}{8} - 1\big)Tr_{\rm ad}\frac{1}{\mathcal{D}^2}\mathcal{F}_{ij}\frac{1}{\mathcal{D}^2}\mathcal{F}_{ij} + ... \\ &= S + 2\big(1 - \frac{d-2}{8}\big)\int_p Tr|\tilde{F}_{ij}(p)|^2\int_k \frac{1}{k^2}\frac{1}{(p-k)^2}(1-\cos\theta_{ij}p_ik_j)|. \quad (2.25)\end{aligned}$$

This correction is the only one-loop contribution which contains a quadratic term in the gauge field. The planar and non-planar corrections to the vacuum polarization are given in this case by

$$\Pi^{\rm P} = \int_k \frac{1}{k^2}\frac{1}{(p-k)^2} = \frac{1}{(4\pi)^{\frac{d}{2}}}\int_0^1 dx\int_0^\infty \frac{dt}{t^{\frac{d}{2}-1}}\, e^{-x(1-x)p^2t}. \quad (2.26)$$

$$\Pi^{\rm NP} = \int_k \frac{1}{k^2}\frac{1}{(p-k)^2}\cos\theta_{ij}p_ik_j = \frac{1}{(4\pi)^{\frac{d}{2}}}\int_0^1 dx\int_0^\infty \frac{dt}{t^{\frac{d}{2}-1}}\, e^{-x(1-x)p^2t - \frac{(\theta_{ij}p_i)^2}{4t}}. \quad (2.27)$$

The planar correction is UV divergent coming from the limit $t \longrightarrow 0$. Indeed we compute (including also an arbitrary mass scale μ and defining $\epsilon = 2 - \frac{d}{2}$)

$$\begin{aligned}\Pi^{\rm P} &= \frac{1}{(4\pi)^{\frac{d}{2}}}\int_0^1 dx\ (\mu^2)^{\frac{d}{2}-2}(x(1-x)\frac{p^2}{\mu^2})^{\frac{d}{2}-2}\ \Gamma(2-\frac{d}{2}) \\ &= \frac{(\mu^2)^{-\epsilon}}{(4\pi)^{\frac{d}{2}}}\Big[\frac{1}{\epsilon} - \gamma - \int_0^1 dx\ln x(1-x)\frac{p^2}{\mu^2} + O(\epsilon)\Big]. \quad (2.28)\end{aligned}$$

The singular high energy behaviour is thus logarithmically divergent. The planar correction needs therefore a renormalization. We add the counter term

$$\delta S = -2(1-\frac{d-2}{8})\frac{(\mu^2)^{-\epsilon}}{(4\pi)^{\frac{d}{2}}}\frac{1}{\epsilon}\int d^dx F_{ij}^2 = -2(1-\frac{d-2}{8})\frac{(\mu^2)^{-\epsilon}}{(4\pi)^{\frac{d}{2}}}\frac{1}{\epsilon}\int_p |\tilde{F}_{ij}(p)|^2. \quad (2.29)$$

The effective action at one-loop is obtained by adding (2.25) and the counter term (2.29). We get

$$\Gamma^{'}_{\rm ren} = \int_p \frac{1}{2g^2(\mu)}|\tilde{F}_{ij}(p)|^2. \quad (2.30)$$

$$\begin{aligned}\frac{1}{2g^2(\mu)} &= \frac{1}{2g^2} + 2(1-\frac{d-2}{8})(\Pi^{\rm P} - \Pi^{\rm NP}) - 2(1-\frac{d-2}{8})\frac{(\mu^2)^{-\epsilon}}{(4\pi)^{\frac{d}{2}}}\frac{1}{\epsilon} \\ &= \frac{1}{2g^2} + \frac{3}{2}\frac{1}{(4\pi)^2}\Big[-\gamma - \int_0^1 dx\ln x(1-x)\frac{p^2}{\mu^2}\Big] - \frac{3}{2}\Pi^{\rm NP}. \quad (2.31)\end{aligned}$$

This equation means that the gauge coupling constant runs with the renormalization scale. The beta function is non-zero given by

$$\beta(g(\mu)) = \mu \frac{dg(\mu)}{d\mu} = -\frac{3}{16\pi^2} g^3(\mu). \tag{2.32}$$

The non-planar correction is UV finite. Indeed we compute the closed expression

$$\Pi^{\rm NP} = \frac{2}{(4\pi)^2} \int_0^1 dx K_0(z) \ , \ z^2 = (\theta_{ij} p_i)^2 x(1-x) p^2. \tag{2.33}$$

In the limit $\theta \longrightarrow 0$ and/or $p \longrightarrow 0$ we can use $K_0(z) = -\ln \frac{z}{2}$ and obtain the IR singular behaviour

$$\Pi^{\rm NP} = -\frac{1}{(4\pi)^2} \int_0^1 dx \ln \frac{(\theta_{ij} p_i)^2 x(1-x) p^2}{4}. \tag{2.34}$$

In summary although the Moyal-Weyl geometry is made stable at one-loop order by the introduction of supersymmetry we still have a UV-IR mixing in the quantum gauge theory. The picture that supersymmetry will generally stabilize the geometry will be confirmed nonperturbatively in this article whereas the precise connection to the UV-IR mixing remains unclear.

3 Fuzzy Spaces

3.1 The Fuzzy Sphere

The ordinary sphere S^2 is defined in global coordinates by the equation

$$\vec{n} \in \mathbf{R}^3 \ , \ \sum_{a=1}^{3} n_a^2 = 1. \tag{3.1}$$

A general function can be expanded in terms of spherical harmonics

$$f(\vec{n}) = \sum_{k=0}^{\infty} f_{km} Y_{km}(\vec{n}). \tag{3.2}$$

Global derivations are given by the generators of rotations in the adjoint representation of the $SU(2)$ group, namely

$$\mathcal{L}_a = -i\epsilon_{abc} n_b \partial_c \ , \ [\mathcal{L}_a, \mathcal{L}_b] = i\epsilon_{abc} \mathcal{L}_c. \tag{3.3}$$

The Laplacian is given by

$$\mathcal{L}^2 = \mathcal{L}_a \mathcal{L}_a \ , \ \text{eigenvalues } l(l+1) \ , l = 0, ..., \infty. \tag{3.4}$$

According to [79, 197] all the geometry of the sphere is encoded in the K-cycle or spectral triple $(\mathcal{A}, \mathcal{H}, \mathcal{L}^2)$. $\mathcal{A} = C^\infty(S^2)$ is the algebra of all functions f of the form (3.2) and $\mathcal{H}$ is the infinite dimensional Hilbert space of square integrable functions on which the

functions are represented. In order to encode the geometry of the sphere in the presence of spin structure we use instead the K-cycle $(\mathcal{A},\mathcal{H},\mathcal{D},\gamma)$ [23] where γ and $\mathcal{D}$ are the chirality and the Dirac operators on the sphere. Remark in particular that

$$Y_{11}\propto n_1+in_2\ ,\ Y_{10}\propto n_3\ ,Y_{1-1}\propto n_1-in_2. \tag{3.5}$$

The fuzzy sphere is a particular deformation of the above triple which is based on the fact that the sphere is the co-adjoint orbit $SU(2)/U(1)$, namely

$$g\sigma_3 g^{-1}=n_a\sigma_a\ ,\ g\in SU(2)\ ,\ \vec{n}\in S^2. \tag{3.6}$$

This also means that S^2 is a symplectic manifold and hence it can be quantized in a canonical fashion by simply quantizing the volume form

$$\omega=\sin\theta d\theta\wedge d\phi\ =\frac{1}{2}\epsilon_{abc}n_a dn_b\wedge dn_c. \tag{3.7}$$

The result of this quantization is to replace the algebra $C^\infty(S^2)$ by the algebra of matrices Mat_{L+1}.

Mat_{L+1} is the algebra of $(L+1)\times(L+1)$ matrices which acts on an $(L+1)-$dimensional Hilbert space H_L with inner product $(f,g)=\frac{1}{L+1}Tr(f^+g)$ where $f,g\in Mat_{L+1}$. The spin $s=L/2$ IRR of $SU(2)$ is found to act naturally on this Hilbert space. The generators are

$$[L_a,L_b]=i\epsilon_{abc}L_c\ ,\ \sum_a L_a^2=c_2\equiv\frac{L}{2}(\frac{L}{2}+1). \tag{3.8}$$

Generally the spherical harmonics $Y_{km}(\vec{n})$ become the canonical $SU(2)$ polarization tensors $\hat{Y}_{km}$ [198]. They are defined by

$$[L_a,[L_a,\hat{Y}_{lm}]]=l(l+1)\hat{Y}_{lm}\ ,\ [L_\pm,\hat{Y}_{lm}]=\sqrt{(l\mp m)(l\pm m+1)}\hat{Y}_{lm\pm1}\ ,\ [L_3,\hat{Y}_{lm}]=m\hat{Y}_{lm} \tag{3.9}$$

They also satisfy

$$\hat{Y}^+_{lm}=(-1)^m\hat{Y}_{l-m}\ ,\ \frac{1}{L+1}Tr\hat{Y}_{l_1m_1}\hat{Y}_{l_2m_2}=(-1)^{m_1}\delta_{l_1l_2}\delta_{m_1,-m_2}. \tag{3.10}$$

Matrix coordinates on $\mathbf{S}^2_L$ are defined by the $k=1$ tensors as in the continuum, namely

$$x_1^2+x_2^2+x_3^2=1\ ,\ [x_a,x_a]=\frac{i}{\sqrt{c_2}}\epsilon_{abc}x_c,\ x_a=\frac{L_a}{\sqrt{c_2}}. \tag{3.11}$$

"Fuzzy" functions on $\mathbf{S}^2_L$ are linear operators in the matrix algebra while derivations are inner defined by the generators of the adjoint action of $SU(2)$, i.e.

$$\mathcal{L}_a(\phi)\equiv[L_a,\phi]. \tag{3.12}$$

A natural choice of the Laplacian operator Δ on the fuzzy sphere is therefore given by the following Casimir operator

$$\Delta_L=\mathcal{L}_a^2\equiv[L_a,[L_a,..]]. \tag{3.13}$$

Thus the algebra of matrices Mat_{L+1} decomposes under the action of the group $SU(2)$ as

$$\frac{L}{2}\otimes\frac{L}{2}=0\oplus 1\oplus 2\oplus..\oplus L. \tag{3.14}$$

The first $L/2$ stands for the left action of the group while the other $L/2$ stands for the right action. It is not difficult to convince ourselves that this Laplacain has a cut-off spectrum of the form $l(l+1)$ where $l=0,1,...,L$. As a consequence a general function on $\mathbf{S}_N^2$ can be expanded in terms of polarization tensors as follows

$$f=\sum_{l=0}^{L}\sum_{m=-l}^{l}f_{lm}\hat{Y}_{lm}. \tag{3.15}$$

The fact that the summation over l involves only angular momenta which are $\leq L$ originates of course from the fact that the spectrum $l(l+1)$ of the Laplacian Δ is cut-off at $l=L$.

The commutative continuum limit is given by $L\longrightarrow\infty$. This is the first limit of interest to us in this article. Therefore the fuzzy sphere is a sequence of the following triples

$$(Mat_{L+1},H_L,\Delta_L). \tag{3.16}$$

Again in the presence of spin structure the fuzzy sphere $\mathbf{S}_L^2$ will be defined instead by the K-cycle $(\mathbf{A},\mathbf{H},D,\Gamma)$ where the chirality operator Γ and the Dirac operator D are given for example in [100] and references therein.

3.2 Fuzzy $\mathbf{CP}^2$

In this section we will give the K-cycle associated with the classical Kähler manifold $\mathbf{CP}^2$ (which is also the co-adjoint orbit $SU(3)/U(2)$) as a limit of the K-cycle which defines fuzzy (or quantized) $\mathbf{CP}^2$ when the noncommutativity parameter goes to 0. We will follow the construction of [134].

Let T_a, $a=1,...,8$ be the generators of $SU(3)$ in the symmetric irreducible representation $(n,0)$ of dimension $N=\frac{1}{2}(n+1)(n+2)$. They satisfy

$$[T_a,T_b]=if_{abc}T_c\ . \tag{3.17}$$

$$T_a^2=\frac{1}{3}n(n+3)\equiv|n|^2\ ,\ d_{abc}T_aT_b=\frac{2n+3}{6}T_c. \tag{3.18}$$

Let $t_a=\lambda_a/2$ (where λ_a are the usual Gell-Mann matrices) be the generators of $SU(3)$ in the fundamental representation $(1,0)$ of dimension $N=3$. They satisfy

$$\begin{aligned}2t_at_b&=\frac{1}{3}\delta_{ab}+(d_{abc}+if_{abc})t_c\\ tr_3t_at_b&=\frac{1}{2}\delta_{ab}\ ,\ tr_3t_at_bt_c=\frac{1}{4}(d_{abc}+if_{abc}).\end{aligned} \tag{3.19}$$

The $N-$dimensonal generator T_a can be obtained by taking the symmetric product of n copies of the fundamental $3-$dimensional generator t_a, viz

$$T_a=(t_a\otimes\mathbf{1}\otimes...\otimes\mathbf{1}+\mathbf{1}\otimes t_a\otimes...\otimes\mathbf{1}+...+\mathbf{1}\otimes\mathbf{1}\otimes...\otimes t_a)_{\text{symmetric}}. \tag{3.20}$$

In the continuum $\mathbf{CP}^2$ is the space of all unit vectors $|\psi>$ in $\mathbf{C}^3$ modulo the phase. Thus $e^{i\theta}|\psi>$, for all $\theta\in[0,2\pi[$ define the same point on $\mathbf{CP}^2$. It is obvious that all these vectors $e^{i\theta}|\psi>$ correspond to the same projector $P=|\psi><\psi|$. Hence $\mathbf{CP}^2$ is the space of all projection operators of rank one on $\mathbf{C}^3$. Let $\mathbf{H}_N$ and $\mathbf{H}_3$ be the Hilbert spaces of the $SU(3)$ representations $(n,0)$ and $(1,0)$ respectively. We will define fuzzy $\mathbf{CP}^2$ through the canonical $SU(3)$ coherent states as follows. Let $\vec{n}$ be a vector in $\mathbf{R}^8$, then we define the projector

$$P_3=\frac{1}{3}\mathbf{1}+n_at_a \tag{3.21}$$

The requirement $P_3^2=P_3$ leads to the condition that $\vec{n}$ is a point on $\mathbf{CP}^2$ satisfying the equations

$$[n_a,n_b]=0\ ,\ n_a^2=\frac{4}{3}\ ,\ d_{abc}n_an_b=\frac{2}{3}n_c. \tag{3.22}$$

We can write

$$P_3=|\vec{n},3><3,\vec{n}|. \tag{3.23}$$

We think of $|\vec{n},3>$ as the coherent state in $\mathbf{H}_3$ (level 3×3 matrices) which is localized at the point $\vec{n}$ of $\mathbf{CP}^2$. Therefore the coherent state $|\vec{n},N>$ in $\mathbf{H}_N$ (level $N\times N$ matrices) which is localized around the point $\vec{n}$ of $\mathbf{CP}^2$ is defined by the projector

$$P_N=|\vec{n},N><N,\vec{n}|=(P_3\otimes P_3\otimes ...\otimes P_3)_{\text{symmetric}}. \tag{3.24}$$

We compute that

$$tr_3t_aP_3=<\vec{n},3|t_a|\vec{n},3>=\frac{1}{2}n_a\ ,\ tr_NT_aP_N=<\vec{n},N|T_a|\vec{n},N>=\frac{n}{2}n_a. \tag{3.25}$$

Hence it is natural to identify fuzzy $\mathbf{CP}^2$ at level $N=\frac{1}{2}(n+1)(n+2)$ (or $\mathbf{CP}^2_N$) by the coordinates operators

$$x_a=\frac{2}{n}T_a. \tag{3.26}$$

They satisfy

$$[x_a,x_b]=\frac{2i}{n}f_{abc}x_c\ ,\ x_a^2=\frac{4}{3}(1+\frac{3}{n})\ ,\ d_{abc}x_ax_b=\frac{2}{3}(1+\frac{3}{2n})x_c. \tag{3.27}$$

Therefore in the large N limit we can see that the algebra of x_a reduces to the continuum algebra of n_a. Hence $x_a\longrightarrow n_a$ in the continuum limit $N\longrightarrow\infty$.

The algebra of functions on fuzzy $\mathbf{CP}^2_N$ is identified with the algebra of $N\times N$ matrices Mat_N generated by all polynomials in the coordinates operators x_a. Recall that $N=\frac{1}{2}(n+1)(n+2)$. The left action of $SU(3)$ on this algebra is generated by $(n,0)$ whereas

the right action is generated by $(0,n)$. Thus the algebra Mat_N decomposes under the action of $SU(3)$ as

$$(n,0)\otimes(0,n) = \otimes_{p=0}^{n}(p,p). \tag{3.28}$$

A general function on fuzzy $\mathbf{CP}^2_N$ is therefore written as

$$F = \sum_{p=0}^{n} F^{(p)}_{I^2,I_3,Y} T^{(p,p)}_{I^2,I_3,Y}. \tag{3.29}$$

The $T^{(p,p)}_{I^2,I_3,Y}$ are $SU(3)$ matrix polarization tensors in the irreducible representation (p,p). I^2, I_3 and Y are the square of the isospin, the third component of the isospin and the hypercharge quantum numbers which characterize $SU(3)$ representations.

The derivations on fuzzy $\mathbf{CP}^2_N$ are defined by the commutators $[T_a, ..]$. The Laplacian is then obviously given by $\Delta_N = [T_a, [T_a, ...]]$. Fuzzy $\mathbf{CP}^2_N$ is completely determined by the spectral triple $\mathbf{CP}^2_N = (Mat_N, \Delta_N, \mathbf{H}_N)$. Now we can compute

$$tr_N F P_N =< \vec{n}, N|F|\vec{n}, N >= F_N(\vec{n}) = \sum_{p=0}^{n} F^{(p)}_{I^2,I_3,Y} Y^{(p,p)}_{I^2,I_3,Y}(\vec{n}). \tag{3.30}$$

The $Y^{(p,p)}_{I^2,I_3,Y}(\vec{n})$ are the $SU(3)$ polarization tensors defined by

$$Y^{(p,p)}_{I^2,I_3,Y}(\vec{n}) =< \vec{n}, N|T^{(p,p)}_{I^2,I_3,Y}|\vec{n}, N > . \tag{3.31}$$

Furthermore we can compute

$$tr_N [T_a, F] P_N =< \vec{n}, N|[T_a, F]|\vec{n}, N >= (\mathcal{L}_a F_N)(\vec{n}) \ , \ \mathcal{L}_a = -if_{abc} n_b \partial_c. \tag{3.32}$$

And

$$tr_N F G P_N =< \vec{n}, N|FG|\vec{n}, N >= F_N * G_N(\vec{n}). \tag{3.33}$$

The star product on fuzzy $\mathbf{CP}^2_N$ is found to be given by (see below)

$$F_N * G_N(\vec{n}) = \sum_{p=0}^{n} \frac{(n-p)!}{p!n!} K_{a_1 b_1} ... K_{a_p b_p} \partial_{a_1} ... \partial_{a_p} F_N(\vec{n}) \partial_{b_1} ... \partial_{b_p} G_N(\vec{n})$$
$$K_{ab} = \frac{2}{3}\delta_{ab} - n_a n_b + (d_{abc} + if_{abc}) n_c. \tag{3.34}$$

3.3 Star Products on Fuzzy $\mathbf{CP}^{N-1}$

The sphere is the complex projective space $\mathbf{CP}^1$. The quantization of higher $\mathbf{CP}^{N-1}$ with $N > 2$ is very similar to the quantization of $\mathbf{CP}^1$, and yields fuzzy $\mathbf{CP}^{N-1}_L$. In this

section we will explain this result by constructing the coherent states [190–192], the Weyl map [193] and star products [194–196] on all fuzzy $\mathbf{CP}_L^{N-1}$ following [134].

We start with classical $\mathbf{CP}^{N-1}$ defined by the projectors[1]

$$P = \frac{1}{N}\mathbf{1} + \alpha_N n^a t_a \ , \ \alpha_N = -\sqrt{\frac{2(N-1)}{N}}. \tag{3.35}$$

The requirement $P^2 = P$ will lead to the defining equations of $\mathbf{CP}^{N-1}$ as embedded in $\mathbf{R}^{N^2-1}$ given by

$$n_a^2 = 1 \ , \ d_{abc} n_a n_b = \frac{2}{\alpha_N}\frac{N-2}{N} n_c. \tag{3.36}$$

The fundamental representation $\mathbf{N}$ of $SU(N)$ is generated by the Lie algebra of Gell-Mann matrices $t_a = \frac{\lambda_a}{2}, a = 1, ..., N^2-1$. These matrices satisfy

$$\begin{aligned} &[t_a, t_b] = i f_{abc} t_c \\ &2 t_a t_b = \frac{1}{N}\delta_{ab}\mathbf{1} + (d_{abc} + i f_{abc}) t_c \\ &Tr t_a t_b t_c = \frac{1}{4}(d_{abc} + i f_{abc}) \ , \ Tr t_a t_b = \frac{\delta_{ab}}{2} \ , \ Tr t_a = 0. \end{aligned} \tag{3.37}$$

Let us specialize the projector (3.35) to the "north" pole of $\mathbf{CP}^{N-1}$ given by the point $\vec{n}_0 = (0, 0, ..., 1)$. We have then the projector $P_0 = \frac{1}{N}\mathbf{1} + \alpha_N t_{N^2-1} = \mathrm{diag}(0, 0, ..., 1)$. So at the "north" pole P projects down onto the state $|\psi_0> = (0, 0, ..., 1)$ of the Hilbert space $\mathbf{C}^N$ on which the defining representation of $SU(N)$ is acting .

A general point $\vec{n} \in \mathbf{CP}^{N-1}$ can be obtained from $\vec{n}_0$ by the action of an element $g \in SU(N)$ as $\vec{n} = g\vec{n}_0$. P will then project down onto the state $|\psi> = g|\psi_0>$ of $\mathbf{C}^N$. One can show that

$$P = |\psi><\psi| = g|\psi_0><\psi_0|g^+ = gP_0g^+. \tag{3.38}$$

$$g t_{N^2-1} g^+ = n^a t_a. \tag{3.39}$$

This last equation is the usual definition of $\mathbf{CP}^{N-1}$. Under $g \longrightarrow gh$ where $h \in U(N-1)$ we have $h t_{N^2-1} h^+ = t_{N^2-1}$, i.e $U(N-1)$ is the stability group of t_{N^2-1} and hence

$$\mathbf{CP}^{N-1} = SU(N)/U(N-1). \tag{3.40}$$

Thus points $\vec{n}$ of $\mathbf{CP}^{N-1}$ are then equivalent classes $[g] = [gh], h \in U(N-1)$.

The fuzzy sphere $\mathbf{S}_L^2$ is the algebra of operators acting on the Hilbert space $H_s^{(2)}$ which is the $(2s+1)-$dimensional irreducible representation of $SU(2)$. This representation can be obtained from the symmetric product of $L = 2s$ fundamental representations $\mathbf{2}$ of $SU(2)$. Indeed given any element $g \in SU(2)$ its $s-$representation matrix $U^{(s)}(g)$ can be obtained as follows

$$U^{(s)}(g) = U^{(\mathbf{2})}(g) \otimes_s ... \otimes_s U^{(\mathbf{2})}(g), 2s - \text{times}. \tag{3.41}$$

[1]In this section we use N to denote the dimension of the space instead of the size of the matrix approximation.

$U^{(\mathbf{2})}(g)$ is the spin 1/2 representation of $g \in SU(2)$.

Similarly fuzzy $\mathbf{CP}_L^{N-1}$ is the algebra of operators acting on the Hilbert space $H_s^{(N)}$ which is the $d_s^{(N)}$-dimensional irreducible reprsentation of $SU(N)$. This dimension is given explicitly by

$$d_s^{(N)} = (\frac{(N-1+2s)!}{(N-1)!(2s)!}. \tag{3.42}$$

Also this $d_s^{(N)}$-dimensional irreducible representation of $SU(N)$ can be obtained from the symmetric product of $L = 2s$ fundamental representations $\mathbf{N}$ of $SU(N)$.

Remark that for $s = 1/2$ we have $d_{1/2}^{(N)} = N$ and therefore $H_{1/2}^{(N)} = \mathbf{C}^N$ is the fundamental representation of $SU(N)$. Clearly the states $|\psi_0>$ and $|\psi>$ of $H_{1/2}^{(N)}$ will correspond in $H_s^{(N)}$ to the two states $|\vec{n}_0, s>$ and $|\vec{n}, s>$ respectively so that $|\psi_0>=|\vec{n}_0, \frac{1}{2}>$ and $|\psi>=|\vec{n}, \frac{1}{2}>$. Furthermore the equation $|\psi>=g|\psi_0>$ becomes

$$|\vec{n}, s>= U^{(s)}(g)|\vec{n}_0, s> . \tag{3.43}$$

$U^{(s)}(g)$ is the representation given by

$$U^{(s)}(g) = U^{(\mathbf{N})}(g) \otimes_s ... \otimes_s U^{(\mathbf{N})}(g), 2s - \text{times}. \tag{3.44}$$

To any operator $\hat{F}$ on $H_s^{(N)}$ (which can be thought of as a function on fuzzy $\mathbf{CP}_L^{N-1}$) we associate a "classical" function $F_s(\vec{n})$ on a classical $\mathbf{CP}^{N-1}$ by

$$F_s(\vec{n}) =< \vec{n}, s|\hat{F}|\vec{n}, s> . \tag{3.45}$$

The product of two such operators $\hat{F}$ and $\hat{G}$ is mapped to the star product of the corresponding two functions

$$F_s * G_s(\vec{n}) =< \vec{n}, s|\hat{F}\hat{G}|\vec{n}, s> . \tag{3.46}$$

Now we compute this star product in a closed form. First we will use the result that any operator $\hat{F}$ on the Hilbert space $H_s^{(N)}$ admits the expansion

$$\hat{F} = \int_{SU(N)} d\mu(h)\tilde{F}(h)U^{(s)}(h). \tag{3.47}$$

$U^{(s)}(h)$ are assumed to satisfy the normalization

$$TrU^{(s)}(h)U^{(s)}(h') = d_s^{(N)}\delta(h^{-1}h'). \tag{3.48}$$

Using the above two equations one can derive the value of the coefficient $\tilde{F}(h)$ to be

$$\tilde{F}(h) = \frac{1}{d_s^{(N)}} Tr\hat{F}U^{(s)}(h^{-1}). \tag{3.49}$$

Using the expansion (3.47) in (3.45) we get

$$F_s(\vec{n}) = \int_{SU(N)} d\mu(h)\tilde{F}(h)\omega^{(s)}(\vec{n}, h) \ , \ \omega^{(s)}(\vec{n}, h) \ = \ < \vec{n}, s|U^{(s)}(h)|\vec{n}, s> . \tag{3.50}$$

On the other hand using the expansion (3.47) in (3.46) will give

$$F_s * G_s(\vec{n}) = \int\int_{SU(N)} d\mu(h) d\mu(h^{'}) \tilde{F}(h) \tilde{G}(h^{'}) \omega^{(s)}(\vec{n}, hh^{'}). \tag{3.51}$$

The computation of this star product boils down to the computation of $\omega^{(l)}(\vec{n}, hh^{'})$. We have

$$\begin{aligned} \omega^{(s)}(\vec{n}, h) &= < \vec{n}, s|U^{(s)}(h)|\vec{n}, s > \\ &= \left[< \vec{n}, \frac{1}{2}|\otimes_s ... \otimes_s < \vec{n}, \frac{1}{2}| \right] \left[U^{(\mathbf{N})}(h) \otimes_s ... \otimes_s U^{(\mathbf{N})}(h) \right] \left[|\vec{n}, \frac{1}{2} > \otimes_s ... \otimes_s |\vec{n}, \frac{1}{2} > \right] \\ &= [\omega^{(\frac{1}{2})}(\vec{n}, h)]^{2s}. \end{aligned} \tag{3.52}$$

$$\omega^{(\frac{1}{2})}(\vec{n}, h) = < \psi|U^{(\mathbf{N})}(h)|\psi > . \tag{3.53}$$

In the fundamental representation $\mathbf{N}$ of $SU(N)$ we have $U^{(\mathbf{N})}(h) = \exp(im^a t_a) = c(m)\mathbf{1} + is^a(m)t_a$ and therefore

$$\omega^{(\frac{1}{2})}(\vec{n}, h) = < \psi|c(m)\mathbf{1} + is^a(m)t_a|\psi >= c(m) + is^a(m) < \psi|t_a|\psi > . \tag{3.54}$$

$$\begin{aligned} \omega^{(\frac{1}{2})}(\vec{n}, hh^{'}) &= < \psi|U^{(\mathbf{N})}(hh^{'})|\psi > \\ &= < \psi|(c(m)\mathbf{1} + is^a(m)t_a)(c(m^{'})\mathbf{1} + is^a(m^{'})t_a)|\psi > \\ &= c(m)c(m^{'}) + i[c(m)s^a(m^{'}) + c(m^{'})s^a(m)] < \psi|t_a|\psi > \\ &- s^a(m)s^b(m^{'}) < \psi|t_a t_b|\psi > . \end{aligned} \tag{3.55}$$

Now it is not difficult to check that

$$\begin{aligned} < \psi|t_a|\psi > &= Trt_a P = \frac{\alpha_N}{2} n^a \\ < \psi|t_a t_b|\psi > &= Trt_a t_b P = \frac{1}{2N}\delta_{ab} + \frac{\alpha_N}{4}(d_{abc} + if_{abc})n^c. \end{aligned} \tag{3.56}$$

Hence we obtain

$$\omega^{(\frac{1}{2})}(\vec{n}, h) = c(m) + i\frac{\alpha_N}{2}\vec{s}(m).\vec{n}. \tag{3.57}$$

$$\begin{aligned} \omega^{(\frac{1}{2})}(\vec{n}, hh^{'}) &= c(m)c(m^{'}) - \frac{1}{2N}\vec{s}(m).\vec{s}(m^{'}) + i\frac{\alpha_N}{2}\Big[c(m)s^a(m^{'}) \\ &+ c(m^{'})s^a(m) \Big] n^a - \frac{\alpha_N}{4}(d_{abc} + if_{abc})n^c s^a(m) s^b(m^{'}). \end{aligned} \tag{3.58}$$

These two last equations can be combined to get the result

$$\begin{aligned} \omega^{(\frac{1}{2})}(\vec{n}, hh^{'}) - \omega^{(\frac{1}{2})}(\vec{n}, h)\omega^{(\frac{1}{2})}(\vec{n}, h^{'}) &= -\frac{1}{2N}\vec{s}(m).\vec{s}(m^{'}) - \frac{\alpha_N}{4}(d_{abc} + if_{abc})n^c s^a(m) s^b(m^{'}) \\ &+ \frac{\alpha_N^2}{4} n^a n^b s_a(m) s_b(m^{'}). \end{aligned} \tag{3.59}$$

We can remark that in this last equation we have got ride of all reference to c's. We would like also to get ride of all reference to s's. This can be achieved by using the formula

$$s_a(m) = \frac{2}{i\alpha_N}\frac{\partial}{\partial n^a}\omega^{(\frac{1}{2})}(\vec{n},h). \tag{3.60}$$

We get then

$$\omega^{(\frac{1}{2})}(\vec{n},hh^{'}) - \omega^{(\frac{1}{2})}(\vec{n},h)\omega^{(\frac{1}{2})}(\vec{n},h^{'}) \;=\; K_{ab}\frac{\partial}{\partial n^a}\omega^{(\frac{1}{2})}(\vec{n},h)\frac{\partial}{\partial n^b}\omega^{(\frac{1}{2})}(\vec{n},h^{'}). \tag{3.61}$$

$$K_{ab} \;=\; \frac{2}{N\alpha_N^2}\delta_{ab} - n_a n_b + \frac{1}{\alpha_N}(d_{abc} + if_{abc})n^c. \tag{3.62}$$

Therefore we obtain

$$\begin{aligned} F_s * G_s(\vec{n}) \;&=\; \sum_{k=0}^{2s}\frac{(2s)!}{k!(2s-k)!}K_{a_1b_1}....K_{a_kb_k} \\ &\times\; \int_{SU(N)} d\mu(h)\tilde{F}(h)[\omega^{(\frac{1}{2})}(\vec{n},h)]^{2s-k}\frac{\partial}{\partial n^{a_1}}\omega^{(\frac{1}{2})}(\vec{n},h)...\frac{\partial}{\partial n^{a_k}}\omega^{(\frac{1}{2})}(\vec{n},h) \\ &\times\; \int_{SU(N)} d\mu(h^{'})\tilde{G}(h^{'})[\omega^{(\frac{1}{2})}(\vec{n},h^{'})]^{2s-k}\frac{\partial}{\partial n^{b_1}}\omega^{(\frac{1}{2})}(\vec{n},h^{'})...\frac{\partial}{\partial n^{b_k}}\omega^{(\frac{1}{2})}(\vec{n},h^{'}). \end{aligned} \tag{3.63}$$

We have also the formula

$$\frac{(2s-k)!}{(2s)!}\frac{\partial}{\partial n^{a_1}}...\frac{\partial}{\partial n^{a_k}}F_s(\vec{n}) \;=\; \int_{SU(N)} d\mu(h)\tilde{F}(h)[\omega^{(\frac{1}{2})}(\vec{n},h)]^{2s-k}\frac{\partial}{\partial n^{a_1}}\omega^{(\frac{1}{2})}(\vec{n},h)...\frac{\partial}{\partial n^{a_k}}\omega^{(\frac{1}{2})}(\vec{n},h). \tag{3.64}$$

This allows us to obtain the final result [134]

$$F_s * G_s(\vec{n}) = \sum_{k=0}^{2s}\frac{(2s-k)!}{k!(2s)!}K_{a_1b_1}....K_{a_kb_k}\frac{\partial}{\partial n^{a_1}}...\frac{\partial}{\partial n^{a_k}}F_j(\vec{n})\frac{\partial}{\partial n^{b_1}}...\frac{\partial}{\partial n^{b_k}}G_j(\vec{n}). \tag{3.65}$$

Specialization of this result to the sphere is obvious. In the last appendix we will discuss a (seemingly) different star product on the fuzzy sphere which admits a straightforward flattening limit to the star product on the Moyal-Weyl plane.

Let us also do some examples. Derivations on $\mathbf{CP}^{N-1}$ are generated by the vector fields $\mathcal{L}_a = -if_{abc}n_b\partial/\partial n_c$ which satisfy $[\mathcal{L}_a,\mathcal{L}_b] = if_{abc}\mathcal{L}_c$. The corresponding action on the Hilbert space $H_s^{(N)}$ is generated by L_a and is given by

$$< \vec{n},s|U^{(s)}(h^{-1})\hat{F}U^{(s)}(h)|\vec{n},s > = < \vec{n}_0,s|U^{(s)}(g^{-1}h^{-1})\hat{F}U^{(s)}(hg)|\vec{n}_0,s > . \tag{3.66}$$

$U^{(s)}(h)$ is given by $U^{(s)}(h) = \exp(i\eta_a L_a)$. Now if we take η to be small then one computes

$$< \vec{n},s|U^{(s)}(h)|\vec{n},s > = 1 + i\eta_a < \vec{n},s|L_a|\vec{n},s > . \tag{3.67}$$

On the other hand we know that the representation $U^{(s)}(h)$ is obtained by taking the symmetric product of $2s$ fundamental representations $\mathbf{N}$ of $SU(N)$ and hence

$$< \vec{n}, s|U^{(s)}(h)|\vec{n}, s >= (< \vec{n}, \frac{1}{2}|1 + i\eta_a t_a|\vec{n}, \frac{1}{2} >)^{2s} = 1 + i(2s)\eta_a \frac{\alpha_N}{2} n_a. \tag{3.68}$$

In above we have used the facts $L_a = t_a \otimes_s .... \otimes_s t_a$, $|\vec{n}, s >= |\vec{n}, \frac{1}{2} > \otimes_s ... \otimes_s |\vec{n}, \frac{1}{2} >$ and the first equation of (3.56). Finally we get the important result

$$< \vec{n}, s|L_a|\vec{n}, s >= s\alpha_N n_a. \tag{3.69}$$

We define the fuzzy derivative $[L_a, \hat{F}]$ by

$$\begin{aligned} (\mathcal{L}_a F)_s(\vec{n}) &\equiv < \vec{n}, s|[L_a, \hat{F}]|\vec{n}, s > \\ &= s\alpha_N \Big[n_a * F_s(\vec{n}) - F_s * n_a(\vec{n}) \Big] \\ &= i f_{abc} n^c \frac{\partial}{\partial n^b} F_s(\vec{n}). \end{aligned} \tag{3.70}$$

Finally we note the identity

$$\frac{1}{d_s^{(N)}} Tr \hat{F}\hat{G} = \int_{\mathbf{CP}^{N-1}} F_s * G_s(\vec{n}). \tag{3.71}$$

4 Review of Bosonic $D = 3$ Yang-Mills Matrix Models

The principal goal of the present article is the construction of a new nonperturbative method for noncommutative gauge theories with and without supersymmetry based on a class of Yang-Mills matrix models in which the classical minima are given by fuzzy projective spaces. These matrix models are directly related to the celebrated IKKT matrix model [11, 145, 146, 149] in $d = 3$ and $d = 4$ dimensions with mass deformation which may or may not preserve supersymmetry.

The flat IKKT models, i.e. without mass deformation, are obtained by dimensionally reducing U(N) super Yang-Mills theory in flat d dimensions onto a point, i.e. to zero dimension. The dynamical variables are d matrices of size N with action

$$S = -\frac{N}{4} Tr[X_\mu, X_\nu]^2 + Tr\bar{\psi}\Gamma_\mu [X_\mu, \psi]. \tag{4.1}$$

The partition functions of these models are convergent in dimensions $d = 4, 6, 10$ [48–54]. In $d = 3$ the partition function may be made finite by adding appropriate mass deformation consisting of a positive quadratic term in the matrices X_μ which damps flat directions. In $d = 3, 4$ the determinant of the Dirac operator is positive definite [46, 50] and thus there is no sign problem. The IKKT model in $d = 10$ dimensions is also called the IIB matrix model. It is postulated to give a constructive definition of type IIB superstring theory.

Mass deformations such as the Myers term [16] are essential in order to reproduce non-trivial geometrical backgrounds such as the fuzzy sphere in Yang-Mills matrix models.

Supersymmetric mass deformations in Yang-Mills matrix models and Yang-Mills quantum mechanics models are considered for example in [14, 15]. Yang-Mills quantum mechanics models such as the BFSS models [3] in various dimensions are a non-trivial escalation over the IKKT models since they involve time. The BMN model [6] which is the unique maximally supersymmetric mass deformation of the BFSS model in $d = 10$ admits the fuzzy sphere background as a solution of its equations of motion. The BFSS and BMN models are postualted to give a constructive definition of M-theory.

The central motivation behind these proposals of using Yang-Mills matrix models and Yang-Mills quantum mechanics as nonperturbative definitions of M-theory and superstring theory lies in D-brane physics [150–152]. At low energy the theory on the $(p+1)-$dimensional world-volume of N coincident Dp-branes is the reduction to $p+1$ dimensions of 10 dimensional supersymmetric Yang-Mills [4]. Thus we get a $(p+1)$ dimensional vector field together with $9-p$ normal scalar fields which play the role of position coordinates of the coincident N Dp-branes. The case $p = 0$ corresponds to D0-branes. The coordinates become noncommuting matrices.

As we have already said the class of matrix models of interest to us in this article are IKKT matrix models in $d = 3$ and $d = 4$ dimensions with mass deformations. The main reason behind this interest is that these matrix models suffer generically from an emergent geometry transition and as a consequence they are very suited for studying nonperturbatively gauge theory on Moyal-Weyl spaces. Furthermore the supersymmetric versions of these matrix models provide a natural nonperturbative regularization of supersymmetry which is very interesting in its own right. Also since these matrix models are related to large N Yang-Mills theory they are of paramount importance to the string/gauge duality which would allow us to study nonperturbative aspects of gravity from the gauge side of the duality. These motivations can also be found elsewhere, for example in [153–156].

The motivation for studying large N Yang-Mills matrix models with backgrounds given by fuzzy spaces is therefore four-fold:

- 1) This is the correct way of defining nonperturbatively noncommutative gauge theories using random matrix models.
- 2) This provides also a nonperturbative definition of supersymmetry. Indeed supersymmetry in this language may prove to be tractable in Monte Carlo simulation.
- 3) They provide concrete models for emergent geometry. Indeed geometry in transition is possible in all these matrix models.
- 4) These large N Yang-Mills matrix models are also relevant for the string/gauge duality.

Among the tools that can naturally be used in the context of Yang-Mills matrix models are Monte Carlo simulation [157, 158], $1/N$ expansion [132, 159–161], renormalization group equation [162, 163] and random matrix theory [143, 144, 164]. Monte Carlo simulation using the Hybrid Monte Carlo algorithm was adapted to this type of matrix models in [46, 165]. However simulations of matrix models remain much harder than simulations of field theory because of the non-local character of matrix interactions. Renormalization group approach to matrix models can be found for example in [166] and [167–171].

The central result in this review section is as follows. In the case of gauge theory on fuzzy complex projective spaces [172] we will describe how the corresponding matrix models allow for a new transition to and from a new high temperature phase known as Yang-Mills or matrix phase with no background geometrical structure. The low temperature phase is a geometrical one with gauge fields fluctuating on a round complex projective space. We discuss the case of the fuzzy sphere in great detail then towards the end we comment on the other known cases.

Noncommutative gauge theory on the fuzzy sphere was introduced in [147, 148]. As we have already mentioned it was derived as the low energy dynamics of open strings moving in a background magnetic field with $\mathbf{S}^3$ metric in [86–88]. This theory consists of the Yang-Mills term YM which can be obtained from the reduction to zero dimensions of ordinary $U(N)$ Yang-Mills theory in 3 dimensions and a Chern-Simons term CS due to Myers effect [16]. Thus the model contains three $N \times N$ hermitian matrices X_1, X_2 and X_3 with an action given by

$$S = \mathrm{YM} + \mathrm{CS} = -\frac{1}{4} Tr[X_a, X_b]^2 + \frac{2i\alpha}{3} \epsilon_{abc} Tr X_a X_b X_c. \tag{4.2}$$

This model contains beside the usual two dimensional gauge field a scalar fluctuation normal to the sphere which can be given by [200]

$$\Phi = \frac{X_a^2 - \alpha^2 c_2}{2\sqrt{c_2}}. \tag{4.3}$$

The model was studied perturbatively in [59] and in [60, 173]. In particular in [59] the effective action for a non-zero gauge fluctuation was computed at one-loop and shown to contain a gauge invariant UV-IR mixing in the large N limit. Indeed the effective action in the commutative limit was found to be given by the expression

$$\begin{aligned} \Gamma &= \frac{1}{4g^2} \int \frac{d\Omega}{4\pi} F_{ab}(1 + 2g^2\Delta_3) F_{ab} - \frac{1}{4g^2} \epsilon_{abc} \int \frac{d\Omega}{4\pi} F_{ab}(1 + 2g^2\Delta_3) A_c + 2\sqrt{N^2 - 1} \int \frac{d\Omega}{4\pi} \Phi \\ &+ \text{non local quadratic terms.} \end{aligned} \tag{4.4}$$

The 1 in $1 + 2g^2\Delta_3$ corresponds to the classical action whereas $2g^2\Delta_3$ is the quantum correction. This provides a non-local renormalization of the inverse coupling constant $1/g^2$. The last terms in (4.4) are new non-local quadratic terms which have no counterpart in the classical action. The eigenvalues of the operator Δ_3 are given by

$$\begin{aligned} \Delta_3(p) &= \sum_{l_1, l_2} \frac{2l_1 + 1}{l_1(l_1+1)} \frac{2l_2 + 1}{l_2(l_2+1)} (1 - (-1)^{l_1 + l_2 + p}) \left\{ \begin{array}{ccc} p & l_1 & l_2 \\ \frac{L}{2} & \frac{L}{2} & \frac{L}{2} \end{array} \right\}^2 \frac{l_2(l_2+1)}{p^2(p+1)^2} \\ &\times \big(l_2(l_2+1) - l_1(l_1+1) \big) \big) \longrightarrow -\frac{h(p) + 2}{p(p+1)} \ , \ h(p) = -2 \sum_{l=1}^{p} \frac{1}{l}. \end{aligned} \tag{4.5}$$

In above $L + 1 = N$. The 1 in $1 - (-1)^{l_1 + l_2 + p}$ corresponds to the planar contribution whereas $(-1)^{l_1 + l_2 + p}$ corresponds to the non-planar contribution where p is the external

momentum. The fact that $\Delta_3 \neq 0$ in the limit $N \longrightarrow 0$ means that we have a UV-IR mixing problem.

The model YM + CS was solved for $N = 2$ and $N = 3$ in [174]. It was studied nonperturbatively in [58] where the geometry in transition was first observed.

In [57] a generalized model was proposed and studied in which the normal scalar field was suppressed by giving it a quartic potential V with very large mass. This potential on its own is an $O(3)$ random matrix model given by

$$V = N\Big[\frac{m^2}{2c_2}Tr(X_a^2)^2 - \alpha^2\mu Tr(X_a^2)\Big]. \tag{4.6}$$

The parameter μ is fixed such that $\mu = m^2$. The model $S+V$ was studied in [55] and [56] where the instability of the sphere was interpreted along the lines of an emergent geometry phenomena. For vanishing potential $m^2, \mu \longrightarrow 0$ the transition from/to the fuzzy sphere phase was found to have a discontinuity in the internal energy, i.e. a latent heat (figure 1) and a discontinuity in the order parameter (figure 2) indicating that the transition is first order. The order parameter is identified with the radius of the sphere, viz

$$\frac{1}{r} = \frac{1}{Nc_2}TrD_a^2\ ,\ X_a = \alpha D_a. \tag{4.7}$$

From the other hand the specific heat was found to diverge at the transition point from the sphere side while it remains constant from the matrix side (figure 3). This indicates a second order behaviour with critical fluctuations only from one side of the transition. This to our knowledge is quite novel. The scaling of the coupling constant α in the large N limit is found to be given by $\tilde{\alpha} = \alpha\sqrt{N}$. We get the critical value

$$\tilde{\alpha}_s = 2.1 \pm 0.1. \tag{4.8}$$

The different phases of the model are characterized by

fuzzy sphere ($\tilde{\alpha} > \tilde{\alpha}_*$)	matrix phase ($\tilde{\alpha} < \tilde{\alpha}_*$)
$r = 1$	$r = 0$
$C_v = 1$	$C_v = 0.75$

For $m \neq 0$ and/or $\mu \neq 0$ the critical point is replaced by a critical line in the $\tilde{\beta} - t$ plane where $\tilde{\beta}^4 = \tilde{\alpha}^4/(1+m^2)^3$ and $t = \mu(1+m^2)$. In other words for generic values of the parameters the matrix phase persists. The effective potential in these cases was computed in [59]. We find

$$V_{\text{eff}} = \tilde{\alpha}^4\big[\frac{1}{4}\phi^4 - \frac{1}{3}\phi^3 + \frac{m^2}{4}\phi^4 - \frac{\mu}{2}\phi^2\big] + \ln\phi. \tag{4.9}$$

The extrema of the classical potential occur at

$$\phi = \frac{1}{1+m^2}\left\{0,\ \phi_\pm = \frac{1 \pm \sqrt{1+4t}}{2}\right\}. \tag{4.10}$$

For μ positive the global minimum is ϕ_+. The 0 is a local maximum and ϕ_- is a local minimum. In particular for $\mu = m^2$ we obtain the global minimum $\phi_+ = 1$. For μ negative the global minimum is still ϕ_+ but 0 becomes a local minimum and ϕ_- a local maximum. If μ is sent more negative then the global minimum $\phi_+ = 1$ becomes degenerate with $\phi = 0$ at $t = -\frac{2}{9}$ and the maximum height of the barrier is given by $V_- = \tilde{\beta}^4/324$ which occurs at $\phi_- = \frac{1}{3}$. The model has a first order transition at $t = -2/9$ where the classical ground states switches from ϕ_+ for $t > -2/9$ to 0 for $t < 2/9$.

Let us now consider the effect of quantum fluctuations. The condition $V_{\text{eff}}^{'} = 0$ gives us extrema of the model. For large enough $\tilde{\alpha}$ and large enough m and μ it admits two positive solutions. The largest solution can be identified with the ground state of the system. It will determine the radius of the sphere. The second solution is the local maximum (figure 4) of V_{eff} and will determine the height of the barrier. As the coupling is decreased these two solutions merge and the barrier disappears. This is the critical point of the model. For smaller couplings than the critical value $\tilde{\alpha}_*$ the fuzzy sphere solution $D_a = \phi L_a$ no longer exists. Therefore the classical transition described above is significantly affected by quantum fluctuations.

The condition when the barrier disappears is $V_{\text{eff}}^{''} = 0$. At this point the local minimum merges with the local maximum (figure 4). Solving the two equations $V_{\text{eff}}^{'} = V_{\text{eff}}^{''} = 0$ yield the critical value

$$g_*^2 = \frac{1}{\tilde{\alpha}_*^4} = \frac{\phi_*^2(\phi_* + 2\mu)}{8}, \tag{4.11}$$

where

$$\phi_* = \frac{3}{8(1+m^2)}\left[1 + \sqrt{1 + \frac{32\mu(1+m^2)}{9}}\right]. \tag{4.12}$$

If we take μ negative we see that g_* goes to zero at $\mu(1+m^2) = -1/4$ and the critical coupling $\tilde{\alpha}_*$ is sent to infinity and therefore for $\mu(1+m^2) < -\frac{1}{4}$ the model has no fuzzy sphere phase. However in the region $-\frac{1}{4} < \mu(1+m^2) < -\frac{2}{9}$ the action $S+V$ is completely positive. It is therefore not sufficient to consider only the configuration $D_a = \phi L_a$ but rather all $SU(2)$ representations must be considered. Furthermore for large $\tilde{\alpha}$ the ground state will be dominated by those representations with the smallest Casimir. This means that there is no fuzzy sphere solution for $\mu(1+m^2) < -\frac{2}{9}$.

The limit of interest is the limit $\mu = m^2 \longrightarrow \infty$. In this case

$$\phi_* = \frac{1}{\sqrt{2}}\ ,\ \tilde{\alpha}_*^4 = \frac{8}{m^2}. \tag{4.13}$$

This means that the phase transition is located at a smaller value of the coupling constant $\tilde{\alpha}$ as m is increased. In other words the region where the fuzzy sphere is stable is extended to lower values of the coupling.

Nonperturbatively the value $\tilde{\alpha}_s$ defined as the value of $\tilde{\alpha}$ at which curves of the average value of the action $< S >$ for different N cross gives a good estimate of the location of the transition. For large N we observe that the location $\tilde{\alpha}_{\max}$ of the peak in C_v and the minimum $\tilde{\alpha}_{\min}$ coincide and agree well with $\tilde{\alpha}_s$. By extrapolating the measured values of

$\tilde{\alpha}_{\max}$ and $\tilde{\alpha}_{\min}$ to $N = \infty$ we obtain the critical value $\tilde{\alpha}_c$. The critical coupling determined either as $\tilde{\alpha}_c$ or as $\tilde{\alpha}_s$ gives good agreement with (4.13). The phase digaram is given in figure 5.

In the case when we include a potential term with $\mu = m^2$ we also found numerical and analytical evidence [175, 176] for the existence of another transition on the fuzzy sphere which is of the Gross-Witten type [177]. This is a field theory transition which occurs within the fuzzy sphere phase before we reach the matrix phase. We also note that a simplified version of our model with V quartic in the matrices, i.e. $m^2 = 0$ and $\mu \neq 0$ was studied in [178, 179].

In [38] an elegant pure matrix model was shown to be equivalent to a gauge theory on the fuzzy sphere with a very particular form of the potential which in the large N limit leads naturally (at least classically) to a decoupled normal scalar fluctuation. In [175,176] and [39] an alternative model of gauge theory on the fuzzy sphere was proposed in which field configurations live in the Grassmannian manifold $U(2N)/(U(N+1) \times U(N-1))$. In [39] this model was shown to possess the same partition function as commutative gauge theory on the ordinary sphere via the application of the powerful localization techniques [36, 37].

The matrix phase which is also called the Yang-Mills phase is dominated by commuting matrices. It is found that the eigenvalues of the three matrices X_1, X_2 and X_3 are uniformly distributed inside a solid ball in 3 dimensions. This was also observed in higher dimensions in [62]. The eigenvalues distribution of a single matrix say X_3 can then be derived by assuming that the joint eigenvalues distribution of the the three commuting matrices X_1, X_2 and X_3 is uniform. We obtain

$$\rho(x) = \frac{3}{4R^3}(R^2 - x^2). \tag{4.14}$$

The parameter R is the radius of the solid ball. We find numerically the value $R = 2$. A one-loop calculation around the background of commuting matrices gives a value in agreement with this prediction.

These eigenvalues may be interpreted as the positions of D0-branes in spacetime following Witten [4]. In [61] there was an attempt to give this phase a geometrical content along the same lines. However our notion of geometry in this article follows Connes [23] which requires providing the Dirac or Laplacian operator together with the algebra in order to determine the geometry of the space. Therefore for all practical purposes this phase has no geometry since we can not identify a sensible Laplacian acting on commuting matrices.

We recognize two different scaling limits. In the fuzzy sphere phase the matrices X_a define a round sphere with a radius which scales as N in the commutative limit, i.e. they define a two-dimensional plane whereas in the matrix phase they define a solid ball in 3 dimensions. This is the scaling limit of the flat two dimensional plane. In the second scaling limit the scaled matrices D_a define on the other hand a round sphere with finite radius in the fuzzy sphere phase whereas in the matrix phase they give a single point.

The essential ingredient in producing this transition is the Chern-Simons term in the action which is due to the Myers effect. This transition is related to the transition found

in hermitian quartic matrix models. For example the $O(3)$ matrix model given by the potential V does not have any transition but when the Chern-Simons term is added to it we reproduce the one-cut to the two-cut transition. By adding the Yang-Mills terms, i.e. by considering the full model we should then obtain a generalization of the one-cut to the two-cut transition. Indeed the matrix to the fuzzy sphere transition is in fact a one-cut to N-cut transition (figure 6).

The matrix phase should be identified with the one-cut (disordered) phase of the quartic hermitian matrix model. By formally comparing (1.2) and (4.6) we can make the identification $a = -\mu\alpha^2$ and $b = m^2/(2c_2)$. The one-cut phase corresponds to the region $a \geq a_* = -2\sqrt{b}$ or equivalently $\tilde{\alpha}^2 \leq \tilde{\alpha}_*^2$ where

$$\tilde{\alpha}_*^4 = \frac{8m^2}{\mu^2}. \tag{4.15}$$

For $\mu = m^2$ this is precisely the critical point (4.13).

By using the methods of cohomological field theories and topological matrix models employed in [33,34,68], it might be possible to bring the model into the form of a hermitian matrix model with generalized interaction of the form [203]

$$S = NaTrM^2 - Tr_{\mathrm{ad}} \ln(\mathrm{ad}M + b). \tag{4.16}$$

In summary we find for pure gauge models with global $SO(3)$ symmetry an exotic line of discontinuous transitions with a jump in the entropy, characteristic of a 1st order transition, yet with divergent critical fluctuations and a divergent specific heat with critical exponent $\alpha = 1/2$. The low temperature phase (small values of the gauge coupling constant) is a geometrical one with gauge fields fluctuating on a round sphere. As the temperature increased the sphere evaporates in a transition to a pure matrix phase with no background geometrical structure. These models present an appealing picture of a geometrical phase emerging as the system cools and suggests a scenario for the emergence of geometry in the early universe.

Lastly we remark on the effect of fermionic determinants on the transition which is the subject of the remainder of this article. We propose here mass deformed supersymmetric matrix Yang-Mills which are reduced from mass deformed supersymmetric Yang-Mills quantum mechanics as the prime candidates to study the effect of supersymmetry on emergent geometry and vice versa in noncommutative gauge theory. These mass deformed matrix models or quantum mechanics provide also the prime examples of supersymmetric models which can be put on a computer. It is conjectured that supersymmetry will remove the transition and stabilizes completely the geometry against the quantum fluctuations of the noncommutative gauge theory or else supersymmetry may be dynamically broken. Indeed our Monte Carlo results reported here (see section 7) confirms this picture. In [47] a Monte Carlo simulation of a 4 dimensional model with a Chern-Simons term was performed. Although the model was not invariant under (flat) supersymmetry transformations the effect of the added Majorana fermions seemed to stabilize the geometry.

Finally we make few remarks on known analogous results in 4 dimensions. In 4 dimensions we have 2 fuzzy projective spaces, fuzzy $\mathbf{CP}_N^2$ and fuzzy $\mathbf{S}_N^2 \times \mathbf{S}_N^2$. Classical

gauge theory on fuzzy $\mathbf{CP}^2_N$ and fuzzy $\mathbf{S}^2_N \times \mathbf{S}^2_N$ are considered in [180,181] and [182,183] respectively. A Monte Carlo study of the model YM + CS on fuzzy $\mathbf{CP}^2_N$ was conducted in [184]. It is observed that in this model both a fuzzy $\mathbf{CP}^2_N$ phase and a fuzzy sphere phase exist together with the matrix phase. The phase structure is therefore much richer. This was confirmed in [181] with the calculation of the one-loop effective potential of the model YM + CS + V on fuzzy $\mathbf{CP}^2_N$. The one-loop effective potential of the model YM + CS + V on fuzzy $\mathbf{S}^2_N \times \mathbf{S}^2_N$ was computed in [185] and a Monte Carlo study of the same model but with $V = 0$ was performed in [186] with similar conclusions. Fuzzy $\mathbf{S}^2_N \times \mathbf{S}^2_N$ is also considered in [187–189]

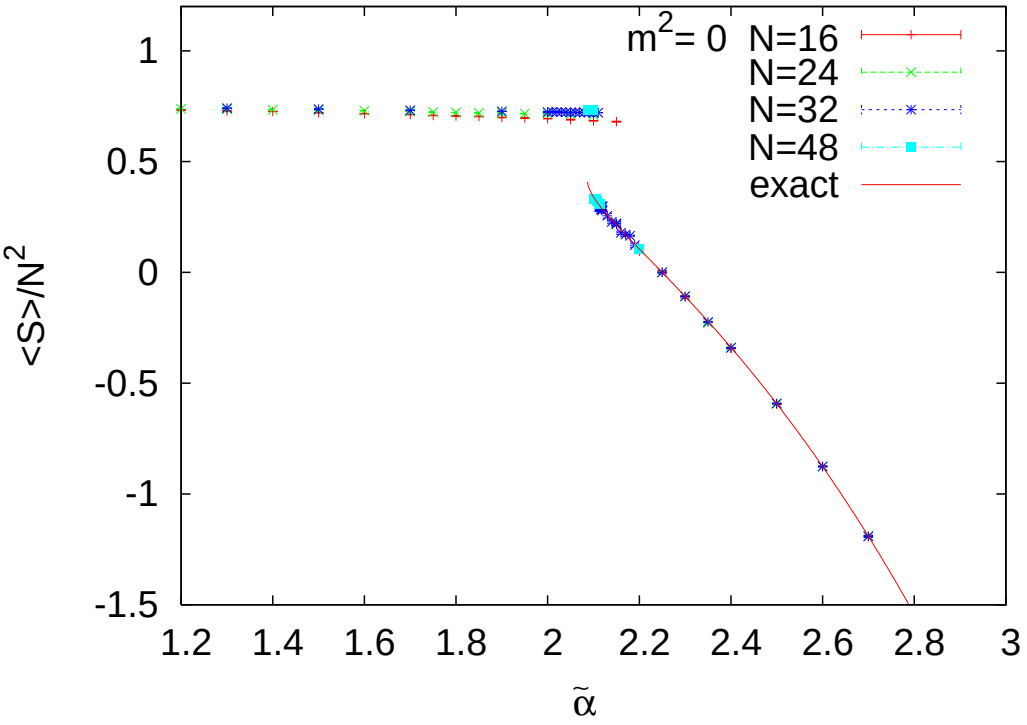

Figure 1: The observable $\frac{<S>}{N^2}$ for $m^2 = 0$ as a function of the coupling constant for different matrix sizes N. The solid line corresponds to the theoretical prediction using the local minimum of the effective potential.

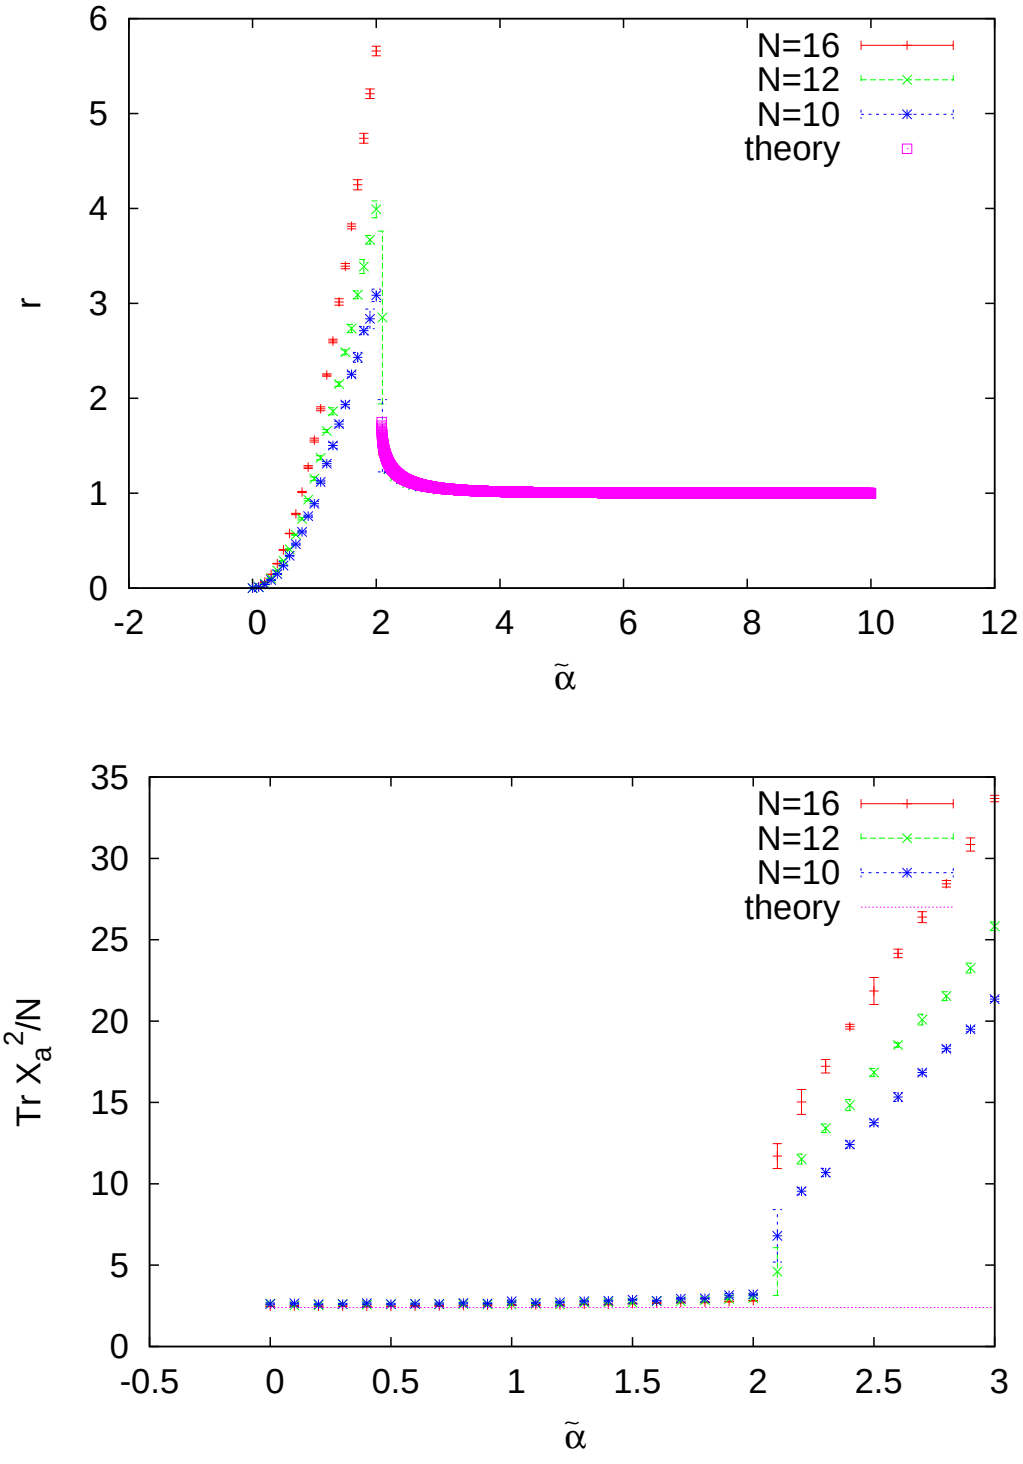

Figure 2: The radius for $m^2 = 0$ as a function of the coupling constant for different matrix sizes N. The theoretical prediction is $r = 1$ in the fuzzy sphere and $TrX_a^2/N = 12/5$ in the matrix phase.

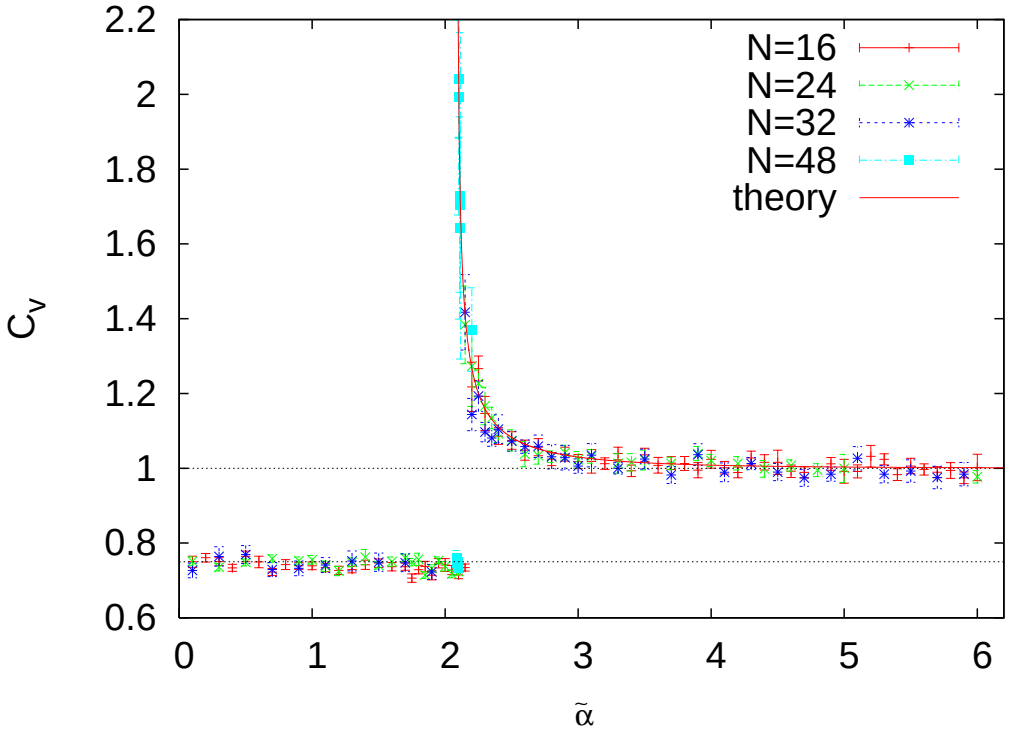

Figure 3: The specific heat for $m^2 = 0$ as a function of the coupling constant for $N = 16, 24, 32, 48$. The curve corresponds with the theoretical prediction for $m^2 = 0$.

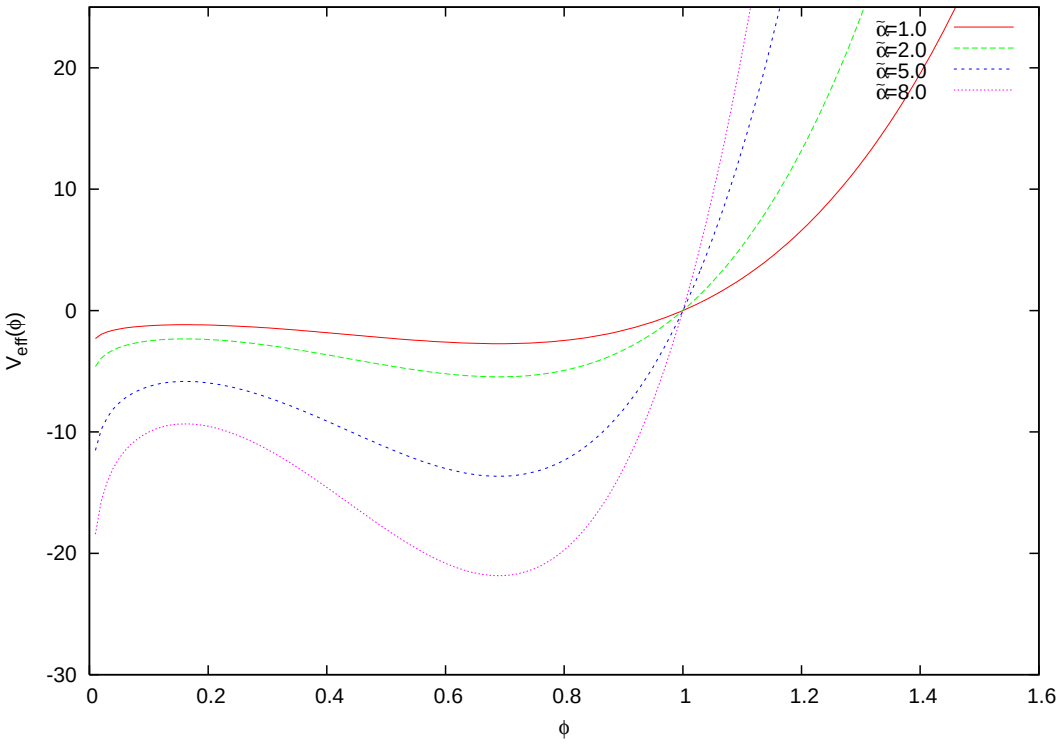

Figure 4: The effective potential for $m^2 = 20$.

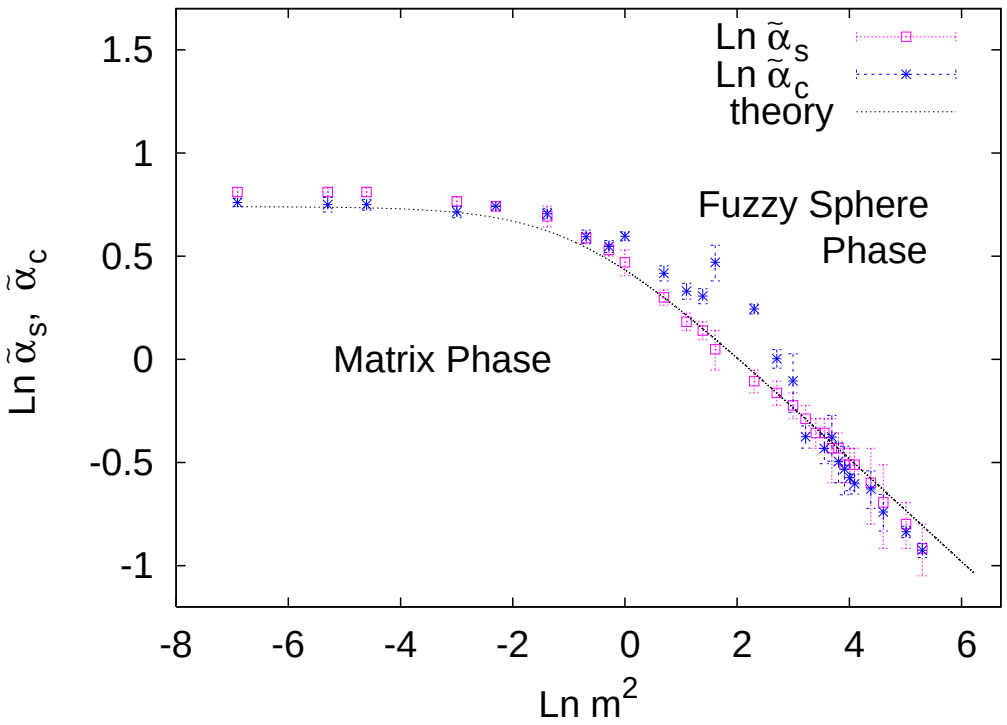

Figure 5: The phase diagram.

5 Mass Deformation of $D = 4$ Super Yang-Mills Matrix Model

5.1 Dimenional Reduction in 4D

We work with the metric $\eta = (-+++)$. The gamma matrices satisfy $\{\gamma_\mu, \gamma_\nu\} = 2\eta_{\mu\nu}$. We consider the representation

$$\gamma^0 = -i \begin{pmatrix} 0 & \mathbf{1}_2 \\ \mathbf{1}_2 & 0 \end{pmatrix} \ , \ \gamma^i = -i \begin{pmatrix} 0 & \sigma_i \\ -\sigma_i & 0 \end{pmatrix}. \tag{5.1}$$

We have $\beta = \gamma_4 = i\gamma^0$, $\gamma_5 = i\gamma_0\gamma_1\gamma_2\gamma_3$. We verify that $\gamma_\mu^+ = \gamma^0\gamma_\mu\gamma^0$, $\gamma_\mu^* = \gamma^2\gamma_\mu\gamma^2$, $\gamma_\mu^T = C\gamma_\mu C$. The charge conjugation matrix is defined by

$$C = \gamma_2\beta = -\epsilon\gamma_5 \ , \ C^+ = C^{-1} = -C \ , \ C^T = -C \ , \ C^2 = -1. \tag{5.2}$$

$$\epsilon = \begin{pmatrix} i\sigma_2 & 0 \\ 0 & i\sigma_2 \end{pmatrix} \ , \ \gamma_5 = \begin{pmatrix} \mathbf{1}_2 & 0 \\ 0 & -\mathbf{1}_2 \end{pmatrix}. \tag{5.3}$$

The Majorana condition reads

$$\bar{\psi} = i\psi^+\gamma^0 \equiv -\psi^T C. \tag{5.4}$$

The $\mathcal{N} = 1$ supersymmetric Yang-Mills theory is given by the Lagrangian density

$$\mathcal{L}_0 = Tr\Big(-\frac{1}{4}F_{\mu\nu}F^{\mu\nu} - \frac{1}{2}\bar{\lambda}\gamma^\mu D_\mu\lambda + \frac{1}{2}D^2\Big). \tag{5.5}$$

$$F_{\mu\nu} = \partial_\mu A_\nu - \partial_\nu A_\mu - ig[A_\mu, A_\nu] \ , \ D_\mu\lambda = \partial_\mu\lambda - ig[A_\mu, \lambda]. \tag{5.6}$$

The supersymmetric transformations are explicitly given by

$$\begin{aligned} &\delta_0 A_\mu = \bar{\epsilon}\gamma_\mu\lambda \\ &\delta_0\lambda = \Big(-\frac{1}{4}[\gamma^\mu, \gamma^\nu]F_{\mu\nu} + i\gamma_5 D\Big)\epsilon \\ &\delta_0 D = i\bar{\epsilon}\gamma_5\gamma_\mu D^\mu\lambda. \end{aligned} \tag{5.7}$$

The reduction of this theory to one dimension is obtained by setting $A_\mu = X_\mu/g$ where $\partial_i X_\mu = 0$. We also set $\lambda = \psi/g$ and $D = F/g$ where $\partial_i\lambda = 0$, $\partial_i F = 0$. We get the supersymmetric Yang-Mills quantum mechanics given by the Lagrangian density

$$\mathcal{L}_0 = \frac{1}{g^2}Tr\Big(\frac{1}{2}(D_0X_i)^2 + \frac{1}{4}[X_i, X_j]^2 - \frac{1}{2}\bar{\psi}\gamma^0 D_0\psi + \frac{i}{2}\bar{\psi}\gamma^i[X_i, \psi] + \frac{1}{2}F^2\Big). \tag{5.8}$$

$$D_0 = \partial_0 - i[X_0, .]. \tag{5.9}$$

The supersymmetric transformations become

$$\begin{aligned}
&\delta_0 X_0 = \bar{\epsilon}\gamma_0\psi \\
&\delta_0 X_i = \bar{\epsilon}\gamma_i\psi \\
&\delta_0\psi = \bigg(-\frac{1}{2}[\gamma^0,\gamma^i]D_0X_i + \frac{i}{4}[\gamma^i,\gamma^j][X_i,X_j] + i\gamma_5 F\bigg)\epsilon \\
&\delta_0 F = -i\bar{\epsilon}\gamma_5\gamma_0 D_0\psi + \bar{\epsilon}\gamma_5\gamma_i[X_i,\psi].
\end{aligned} \tag{5.10}$$

Note that the variation of the Lagrangian density $\mathcal{L}_0$ under the supersymmetry transformations is given by (we set $F=0$ for simplicity)

$$\begin{aligned}
\delta\bigg(Tr\frac{i}{2}\bar{\psi}\gamma^i[X_i,\psi] - Tr\frac{1}{2}\bar{\psi}\gamma^0 D_0\psi + \frac{1}{2}(D_0X_i)^2 + \frac{1}{4}[X_i,X_j]^2\bigg) \quad &= \\
-\frac{1}{3}\bigg[(C\gamma^\rho)_{\alpha\beta}(C\gamma_\rho)_{\mu\nu} + (C\gamma^\rho)_{\beta\nu}(C\gamma_\rho)_{\mu\alpha} \quad &+ \\
(C\gamma^\rho)_{\nu\alpha}(C\gamma_\rho)_{\mu\beta}\bigg]\epsilon_\mu Tr\psi_\alpha\{\psi_\nu,\psi_\beta\}. &
\end{aligned} \tag{5.11}$$

This vanishes by Fierz identity.

5.2 Deformed Yang-Mills Quantum Mechanics in 4D

Let μ be a constant mass parameter. A mass deformation of the Lagrangian density $\mathcal{L}_0$ takes the form

$$\mathcal{L}_\mu = \mathcal{L}_0 + \frac{\mu}{g^2}\mathcal{L}_1 + \frac{\mu^2}{g^2}\mathcal{L}_2 + ... \tag{5.12}$$

The Lagrangian density $\mathcal{L}_0$ has mass dimension 4. The corrections $\mathcal{L}_1$ and $\mathcal{L}_2$ must have mass dimension 3 and 2 respectively. We recall that the Bosonic matrices X_0 and X_a have mass dimension 1 whereas the Fermionic matrices ψ_i have mass dimension $\frac{3}{2}$. A typical term in the Lagrangian densities $\mathcal{L}_1$ and $\mathcal{L}_2$ will contain n_f Fermion matrices, n_b Boson matrices and n_t covariant time derivatives. Clearly for $\mathcal{L}_1$ we must have $\frac{3}{2}n_f+n_b+n_t=3$. There are only three solutions $(n_f,n_b,n_t)=(2,0,0),(0,3,0),(0,2,1)$. For $\mathcal{L}_2$ we must have $\frac{3}{2}n_f+n_b+n_t=2$ and we have only one solution $(n_f,n_b,n_t)=(0,2,0)$. Thus the most general forms of $\mathcal{L}_1$ and $\mathcal{L}_2$ are

$$\mathcal{L}_1 = Tr\bigg(\bar{\psi}M\psi + \frac{1}{3!}S_{abc}X_aX_bX_c + J_{ab}X_aD_0X_b\bigg). \tag{5.13}$$

$$\mathcal{L}_2 = Tr\bigg(-\frac{1}{2!}S_{ab}X_aX_b\bigg). \tag{5.14}$$

Clearly for $\mathcal{L}_3$ we must have $\frac{3}{2}n_f+n_b+n_t=1$ which can not be satisfied. Thus the correction $\mathcal{L}_3$ and all other higher order corrections vanish identically.

We will follow the method of [15] to determine the exact form of the mass deformation. We start with the fermionic mass term

$$\frac{\mu}{g^2}\mathcal{L}_\psi = \frac{\mu}{g^2}Tr\bar{\psi}M\psi = -\mu Tr\bar{\psi}CM^TC\psi. \tag{5.15}$$

We can verify that only the identity matrix, the gamma five and the cubic terms in the gamma matrices can survive in the expansion of M. The cubic terms are either $\gamma^0[\gamma^i,\gamma^j]$ or $\gamma^1\gamma^2\gamma^3$. we have

$$\mathcal{L}_\psi = Tr\bar{\psi}\bigg(ia\mathbf{1}_4 + b\gamma_5 + \frac{1}{2}H_{ij}\gamma^0[\gamma^i,\gamma^j] + c\gamma^1\gamma^2\gamma^3\bigg)\psi. \tag{5.16}$$

Under the chiral transformation $\psi \longrightarrow \chi = e^{i\phi\gamma_5}\psi$, $\bar{\psi} \longrightarrow \bar{\chi} = \bar{\psi}e^{i\phi\gamma_5}$ the Lagrangian density $\mathcal{L}_0$ remains the same while $\mathcal{L}_\psi$ transforms as

$$\mathcal{L}_\psi = Tr\bar{\chi}\bigg(ia^{'}\mathbf{1}_4 + b^{'}\gamma_5 + \frac{1}{2}H_{ij}\gamma^0[\gamma^i,\gamma^j] + c\gamma^1\gamma^2\gamma^3\bigg)\chi, \tag{5.17}$$

where $a^{'} = a\cos 2\phi + b\sin 2\phi$ and $b^{'} = -a\sin 2\phi + b\cos 2\phi$. Thus we can use this symmetry to set $b = 0$. We get

$$\mathcal{L}_\psi = Tr\bar{\psi}\bigg(ia\mathbf{1}_4 + \frac{1}{2}H_{ij}\gamma^0[\gamma^i,\gamma^j] + c\gamma^1\gamma^2\gamma^3\bigg)\psi. \tag{5.18}$$

The numerical coefficients a, H_{ij} and c will be constrained further under the requirement of supersymmetry invariance.

Next we consider the bosonic terms. We can choose the coefficients J_{ab} to be antisymmetric without any loss of generality since we have $\int dt\ TrJ_{ab}X^aD_0X^b = \int dt\ Tr\frac{1}{2}(J_{ab} - J_{ba})X^aD_0X^b - \int Tr\frac{1}{2}D_0J_{ab}X^aX^b$ where clearly the last term can be included in $\mathcal{L}_2$. The Bosonic part of the action reads

$$\frac{1}{g^2}Tr\bigg(\frac{1}{2}(D_0X_a)^2 + \frac{1}{4}[X_a,X_b]^2 + \frac{\mu}{3!}S_{abc}X_aX_bX_c + \mu J_{ab}X_aD_0X_b - \frac{\mu^2}{2!}S_{ab}X_aX_b\bigg). \tag{5.19}$$

We consider the action of a time dependent $SO(3)$ rotation L defined by $Y_a = L_{ab}X_b$, $X_a = L_{ba}Y_b$, $LL^T = L^TL = 1$. The action transforms as

$$\frac{1}{g^2}Tr\bigg(\frac{1}{2}(D_0Y_a)^2 + \frac{1}{4}[Y_a,Y_b]^2 + \frac{\mu}{3!}\hat{S}_{abc}Y_aY_bY_c + \mu\hat{J}_{ab}Y_aD_0Y_b - \frac{\mu^2}{2!}\hat{S}_{ab}Y_aY_b\bigg), \tag{5.20}$$

where $\hat{S}_{abc} = S_{a_0b_0c_0}L_{aa_0}L_{bb_0}L_{cc_0}$, $\hat{S}_{ab} = S_{a_0b_0}L_{aa_0}L_{bb_0} - \frac{2}{\mu}J_{a_0b_0}L_{aa_0}\partial_0L_{bb_0} - \frac{1}{\mu^2}\partial_0L_{ac}\partial_0L_{bc}$, $\hat{J}_{ab} = J_{a_0b_0}L_{aa_0}L_{bb_0} + \frac{1}{\mu}L_{bc}\partial_0L_{ac}$. Thus it is clear that we can choose L such that $\hat{J}_{ab} = 0$.

By similar arguments we can show that the coefficients S_{ab} can be chosen to be totally symmetric while the coefficients S_{abc} can be chosen totally antisymmetric. By rotational invariance we must therefore have $S_{ab} = v\delta_{ab}$ and $S_{abc} = 6ie\epsilon_{abc}$ for some numerical coefficients v and e. In particular the Myers term is

$$\frac{\mu}{g^2}\mathcal{L}_{\text{myers}} = \frac{\mu}{g^2}\bigg(ie\epsilon_{ijk}TrX_iX_jX_k\bigg). \tag{5.21}$$

The mass deformed supersymmetric transformations will be taken such that on bosonic fields they will coincide with the non deformed supersymmetric transformations so that the Fierz identity can still be used. The mass deformed supersymmetric transformations on fermionic fields will be different from the non deformed supersymmetric transformations

with a time dependent parameter $\epsilon \equiv \epsilon(t)$ which satisfies $\partial_0 \epsilon = \mu \Pi \epsilon$. We will suppose the supersymmetric transformations

$$\begin{aligned} \delta_\mu X_0 &= \delta_0 X_0 \\ \delta_\mu X_i &= \delta_0 X_i \\ \delta_\mu \psi &= \delta_0 \psi + \mu \Delta \epsilon. \end{aligned} \tag{5.22}$$

By requiring that the Lagrangian density (5.12) is invariant under these transformations we can determine precisely the form of the mass deformed Lagrangian density and the mass deformed supersymmetry transformations. A long calculation yields the mass deformed Lagrangian density and mass deformed supersymmetry transformations given respectively by (see Appendix C)

$$\mathcal{L}_\mu = \mathcal{L}_0 + \frac{\mu}{g^2} Tr \bar{\psi} \big(ia - \frac{3e}{4} \gamma^1 \gamma^2 \gamma^3 \big) \psi + ie \epsilon_{ijk} \frac{\mu}{g^2} Tr X_i X_j X_k - \frac{\mu^2}{g^2} \frac{1}{2} (e^2 - \frac{16}{9} a^2) Tr X_i^2. \tag{5.23}$$

$$\begin{aligned} \delta_\mu X_0 &= \bar{\epsilon} \gamma_0 \psi \\ \delta_\mu X_i &= \bar{\epsilon} \gamma_i \psi \\ \delta_\mu \psi &= \Big(-\frac{1}{2} [\gamma^0, \gamma^i] D_0 X_i + \frac{i}{4} [\gamma^i, \gamma^j] [X_i, X_j] - \frac{4\mu}{3} \big(ia + \frac{3e}{4} \gamma^1 \gamma^2 \gamma^3 \big) \gamma^i X_i \Big) \epsilon. \end{aligned} \tag{5.24}$$

$$\epsilon \equiv \epsilon(t) = e^{\mu \left(\frac{2ia}{3} \gamma^0 + \frac{e}{2} \gamma^0 \gamma^1 \gamma^2 \gamma^3 \right) t}. \tag{5.25}$$

We verify that $(\delta_\mu X_\mu)^+ = \delta_\mu X_\mu$ and hence the Hermitian matrices X_μ remains Hermitian under supersymmetry. The corresponding supersymmetric algebra is $su(2|1)$ [15].

We prefer to work with the parameters μ_1 and μ_2 defined by $ia\mu = \mu_1/4$ and $-\frac{3e\mu}{4} = \mu_2/4$. The Lagrangian density and supersymmetric transformations become

$$\mathcal{L}_\mu = \mathcal{L}_0 + \frac{1}{4g^2} Tr \bar{\psi} \big(\mu_1 + \mu_2 \gamma^1 \gamma^2 \gamma^3 \big) \psi - i \epsilon_{ijk} \frac{\mu_2}{3g^2} Tr X_i X_j X_k - \frac{1}{18 g^2} (\mu_1^2 + \mu_2^2) Tr X_i^2. \tag{5.26}$$

$$\begin{aligned} \delta_\mu X_0 &= \bar{\epsilon} \gamma_0 \psi \\ \delta_\mu X_i &= \bar{\epsilon} \gamma_i \psi \\ \delta_\mu \psi &= \Big(-\frac{1}{2} [\gamma^0, \gamma^i] D_0 X_i + \frac{i}{4} [\gamma^i, \gamma^j] [X_i, X_j] - \frac{1}{3} \big(\mu_1 - \mu_2 \gamma^1 \gamma^2 \gamma^3 \big) \gamma^i X_i \Big) \epsilon. \end{aligned} \tag{5.27}$$

$$\epsilon \equiv \epsilon(t) = e^{\frac{1}{6} \left(\mu_1 \gamma^0 - \mu_2 \gamma^0 \gamma^1 \gamma^2 \gamma^3 \right) t}. \tag{5.28}$$

5.3 Truncation to Zero Dimension

We consider now the Lagrangian density (action) given by

$$\mathcal{L}_\mu = \mathcal{L}_0 + \frac{a}{4g^2}Tr\bar{\psi}\big(\mu_1 + \mu_2\gamma^1\gamma^2\gamma^3\big)\psi - i\epsilon_{ijk}\frac{b\mu_2}{3g^2}TrX_iX_jX_k - \frac{c}{18g^2}(\mu_1^2+\mu_2^2)TrX_i^2. \tag{5.29}$$

$$\mathcal{L}_0 = \frac{1}{g^2}Tr\bigg(\frac{1}{4}[X_\mu, X_\nu][X^\mu, X^\nu] + \frac{i}{2}\bar{\psi}\gamma^\mu[X_\mu,\psi]\bigg). \tag{5.30}$$

In above we have allowed for the possibility that mass deformations corresponding to the reduction to zero and one dimensions can be different by including different coefficients a, b and c in front of the fermionic mass term, the Myers term and the bosonic mass term respectively. However we will keep the mass deformed supersymmetric transformations unchanged. We have

$$\delta_\mu X_\mu = \bar{\epsilon}\gamma_\mu\psi = -\bar{\psi}\gamma_\mu\epsilon. \tag{5.31}$$

$$\delta_\mu\psi = \bigg(\frac{i}{4}[\gamma^\mu,\gamma^\nu][X_\mu,X_\nu] - \frac{1}{3}\big(\mu_1 - \mu_2\gamma^1\gamma^2\gamma^3\big)\gamma^iX_i\bigg)\epsilon. \tag{5.32}$$

We compute the supersymmetric variations

$$g^2\delta_\mu\mathcal{L}_0 = -\frac{i}{3}Tr\bar{\psi}(\mu_1+\mu_2\gamma^1\gamma^2\gamma^3)\gamma^0\gamma^i[X_0,X_i]\epsilon - \frac{i}{6}Tr\bar{\psi}(\mu_1-\mu_2\gamma^1\gamma^2\gamma^3)[\gamma^i,\gamma^j][X_i,X_j]\epsilon. \tag{5.33}$$

$$\begin{aligned}\delta_\mu\bigg(\frac{a}{4}Tr\bar{\psi}\big(\mu_1+\mu_2\gamma^1\gamma^2\gamma^3\big)\psi\bigg) &= \frac{a}{12}(\mu_1^2+\mu_2^2)Tr\delta_\mu(X_i^2)\\ &+ \frac{ia}{2}Tr\bar{\psi}(\mu_1+\mu_2\gamma^1\gamma^2\gamma^3)\gamma^0\gamma^i[X_0,X_i]\epsilon\\ &+ \frac{ia}{8}Tr\bar{\psi}(\mu_1+\mu_2\gamma^1\gamma^2\gamma^3)[\gamma^i,\gamma^j][X_i,X_j]\epsilon.\end{aligned} \tag{5.34}$$

Clearly the first term of (5.33) must cancel the second term of (5.34), i.e.

$$a = \frac{2}{3}\ ,\ c = 1. \tag{5.35}$$

We get then

$$\begin{aligned}\delta_\mu\bigg(g^2\mathcal{L}_0 + \frac{1}{6}Tr\bar{\psi}\big(\mu_1+\mu_2\gamma^1\gamma^2\gamma^3\big)\psi - \frac{1}{18}(\mu_1^2+\mu_2^2)TrX_i^2\bigg) &=\\ -\frac{i}{6}Tr\bar{\psi}(\mu_1-\mu_2\gamma^1\gamma^2\gamma^3)[\gamma^i,\gamma^j][X_i,X_j]\epsilon &+\\ \frac{i}{12}Tr\bar{\psi}(\mu_1+\mu_2\gamma^1\gamma^2\gamma^3)[\gamma^i,\gamma^j][X_i,X_j]\epsilon.&\end{aligned} \tag{5.36}$$

By using the identity $\frac{1}{2}\gamma^1\gamma^2\gamma^3[\gamma^i,\gamma^j] = -\epsilon_{ijk}\gamma^k$ we find

$$\delta_\mu\Big(- i\epsilon_{ijk}\frac{b\mu_2}{3}TrX_iX_jX_k\Big) \;\; = \;\; -\frac{ib\mu_2}{4}Tr\bar{\psi}\gamma^1\gamma^2\gamma^3[\gamma^i,\gamma^j][X_i,X_j]\epsilon. \qquad (5.37)$$

We must then have

$$b = 1. \qquad (5.38)$$

But also we must have

$$\mu_1 = 0. \qquad (5.39)$$

Thus we get

$$\delta_\mu\Big(g^2\mathcal{L}_0 + \frac{\mu_2}{6}Tr\bar{\psi}\gamma^1\gamma^2\gamma^3\psi - \frac{\mu_2^2}{18}TrX_i^2 - i\epsilon_{ijk}\frac{\mu_2}{3}TrX_iX_jX_k\Big) \;\; = \;\; 0. \qquad (5.40)$$

The model of interest is therefore

$$\begin{aligned}\mathcal{L}_\mu \;\; &= \;\; \frac{1}{g^2}Tr\Big(\frac{1}{4}[X_\mu,X_\nu][X^\mu,X^\nu] + \frac{i}{2}\bar{\psi}\gamma^\mu[X_\mu,\psi] + \frac{\mu_2}{6}Tr\bar{\psi}\gamma^1\gamma^2\gamma^3\psi - \frac{\mu_2^2}{18}TrX_i^2 \\ &- \;\; i\epsilon_{ijk}\frac{\mu_2}{3}TrX_iX_jX_k\Big). \qquad (5.41)\end{aligned}$$

Since ψ and ϵ are Majorana spinors we can rewrite them as

$$\psi = \begin{pmatrix} i\sigma_2(\theta^+)^T \\ \theta \end{pmatrix} \;\; , \;\; \epsilon = \begin{pmatrix} i\sigma_2(\omega^+)^T \\ \omega \end{pmatrix}. \qquad (5.42)$$

We compute with $X_0 = iX_4$ the action

$$\mathcal{L}_\mu \;\; = \;\; \frac{1}{g^2}Tr\Big(\frac{1}{2}[X_4,X_i]^2 + \frac{1}{4}\Big([X_i,X_j] - i\frac{\mu_2}{3}\epsilon_{ijk}X_k\Big)^2 + \theta^+\Big(i[X_4,..] + \sigma_i[X_i,..] + \frac{\mu_2}{3}\Big)\theta\Big). \qquad (5.43)$$

The supersymmetric transformations are

$$\begin{aligned}&\delta_\mu X_0 = i(\omega^+\theta - \theta^+\omega) \\ &\delta_\mu X_i = i(\theta^+\sigma_i\omega - \omega^+\sigma_i\theta) \\ &\delta_\mu\theta = \Big(- i\sigma_i[X_0,X_i] - \frac{1}{2}\epsilon_{ijk}\sigma_k[X_i,X_j] + \frac{i}{3}\mu_2\sigma_iX_i\Big)\omega. \qquad (5.44)\end{aligned}$$

6 Cohomological Approach

6.1 Supersymmetry Transformations

The $\mathcal{N} = 1$ supersymmetric Yang-Mills theory in four dimensions is given by the Lagrangian density

$$\mathcal{L}_0 = Tr\Big(- \frac{1}{4}F_{\mu\nu}F^{\mu\nu} - \frac{1}{2}\bar{\lambda}\gamma^\mu D_\mu\lambda + \frac{1}{2}D^2\Big). \qquad (6.1)$$

$$F_{\mu\nu} = \partial_\mu A_\nu - \partial_\nu A_\mu - ig[A_\mu, A_\nu] \ , \ D_\mu\lambda = \partial_\mu\lambda - ig[A_\mu, \lambda]. \tag{6.2}$$

The supersymmetric transformations are explicitly given by

$$\begin{aligned}
&\delta A_\mu = \bar{\epsilon}\gamma_\mu\lambda \\
&\delta\lambda = \Big(-\frac{1}{4}[\gamma^\mu, \gamma^\nu]F_{\mu\nu} + i\gamma_5 D\Big)\epsilon \\
&\delta D = i\bar{\epsilon}\gamma_5\gamma_\mu D^\mu\lambda.
\end{aligned} \tag{6.3}$$

The Majorana spinors λ and ϵ can be written in terms of two dimensional complex spinors θ and ω as

$$\lambda = -\frac{1}{g}\begin{pmatrix} i\sigma_2(\theta^+)^T \\ \theta \end{pmatrix} \ , \ \epsilon = \begin{pmatrix} i\sigma_2(\omega^+)^T \\ \omega \end{pmatrix}. \tag{6.4}$$

We will also write

$$A_\mu = \frac{1}{g}X_\mu \ , \ D = \frac{2i}{g}B. \tag{6.5}$$

We will work with Euclidean metric, i.e $X_0 = iX_4$. The reduction of the above theory to zero dimension is obtained by setting $\partial_\mu X_4 = 0$, $\partial_\mu X_a = 0$, $\partial_\mu\theta = 0$, $\partial_\mu\theta^+ = 0$ and $\partial_\mu D = 0$. We obtain

$$S \ = \ -\frac{1}{g^2}Tr\Big(\frac{1}{4}[X_\mu, X_\nu]^2 + \bar{\theta}\bar{\sigma}^\mu[X_\mu, \theta] - 2B^2\Big). \tag{6.6}$$

We can also trivially check that (we set $g^2 = 1$)

$$S \ = \ -\frac{1}{4}Tr[X_\mu, X_\nu]^2 - Tr\theta^+\Big(i[X_4, ..] + \sigma_a[X_a, ..]\Big)\theta + 2TrB^2. \tag{6.7}$$

The supersymmetric transformations become

$$\begin{aligned}
&\delta X^\mu = i\bar{\omega}\bar{\sigma}^\mu\theta - i\bar{\theta}\bar{\sigma}^\mu\omega \\
&\delta\theta = i\sigma^{\mu\nu}[X^\mu, X^\nu]\omega - 2B\omega \\
&\delta\bar{\theta} = -i\bar{\omega}\sigma^{\mu\nu}[X^\mu, X^\nu] + 2B\bar{\omega} \\
&\delta B = \frac{1}{2}\bar{\omega}\bar{\sigma}^\mu[X^\mu, \theta] + \frac{1}{2}[X^\mu, \bar{\theta}]\bar{\sigma}^\mu\omega.
\end{aligned} \tag{6.8}$$

Let us note that since we are in Euclidean signature the transformation law of X_4 is antihermitian rather than hermitian.

By using a contour shifting argument for the Gaussian integral over B we can rewrite the auxiliary field B as

$$B = H + \frac{1}{2}[X_1, X_2]. \tag{6.9}$$

The matrix H must be taken hermitian. We will also introduce

$$\theta_1 = \eta_2 + i\eta_1 \ , \ \theta_2 = \chi_1 + i\chi_2. \tag{6.10}$$

$$\phi = \frac{1}{2}(X_3 + iX_4) \ , \ \bar{\phi} = -\frac{1}{2}(X_3 - iX_4). \tag{6.11}$$

Let us now compute

$$S \ = \ 2S_{\rm cohom}. \tag{6.12}$$

$$\begin{aligned} S_{\rm cohom} &= Tr\Big(H^2 + H[X_1, X_2] + [X_i, \phi][X_i, \bar{\phi}] + [\phi, \bar{\phi}]^2 - \eta_i[\phi, \eta_i] - \chi_i[\bar{\phi}, \chi_i] \\ &- \eta_1 \epsilon^{ij}[\chi_i, X_j] + \eta_2[\chi_i, X_i]\Big). \end{aligned} \tag{6.13}$$

In above we have used $\epsilon^{12} = 1$ and the result $TrF_1[B, F_2] = -Tr\{F_1, F_2\}B$ where F_i are fermionic matrices and B is a bosonic matrix. The indices i and j take the values 1 and 2. As we will see ϕ and $\bar{\phi}$ must be taken to be independent. Furthermore ϕ must be taken antihermitian and $\bar{\phi}$ hermitian.

We have four independent real supersymmetries generated by the four independent grassmannian parameters ξ_i, ρ_i defined by the equations $\omega_1 = \xi_2 + i\xi_1$ and $\omega_2 = \rho_1 + i\rho_2$. The supercharges $Q_1 = Q_{1R} + iQ_{1I}$ and $Q_2 = Q_{2R} + iQ_{2I}$ are defined such that the supersymmetric transformation of any operator $\mathcal{O} = \mathcal{O}_I + i\mathcal{O}_R$ is given by

$$\delta\mathcal{O} \ = \ [Q^+\omega - \omega^+ Q, \mathcal{O}] = (\delta\mathcal{O})_R + i(\delta\mathcal{O})_I, \tag{6.14}$$

where

$$(\delta\mathcal{O})_R = -2i[\mathcal{Q}, \mathcal{O}_I] \ , \ (\delta\mathcal{O})_I = 2i[\mathcal{Q}, \mathcal{O}_R]. \tag{6.15}$$

The generator $\mathcal{Q}$ is antihermitian and it can be written as

$$\mathcal{Q} = \xi_2 Q_{1R} + \xi_1 Q_{1I} + \rho_1 Q_{2R} + \rho_2 Q_{2I}. \tag{6.16}$$

For a bosonic field $\mathcal{O}$ the imaginary part $\mathcal{O}_I$ is zero and thus we obatin $(\delta\mathcal{O})_I = 2i[\mathcal{Q}, \mathcal{O}] = \hat{\delta}\mathcal{O} = -i\delta\mathcal{O}$. After a long calculation we obtain

$$\begin{aligned} \hat{\delta}X_1 &= 2\big(\xi_2\chi_1 + \xi_1\chi_2 + \rho_1\eta_2 + \rho_2\eta_1\big) \\ \hat{\delta}X_2 &= 2\big(\xi_2\chi_2 - \xi_1\chi_1 + \rho_2\eta_2 - \rho_1\eta_1\big). \end{aligned} \tag{6.17}$$

$$\begin{aligned} \hat{\delta}\phi &= -2\big(\rho_1\chi_1 + \rho_2\chi_2\big) \\ \hat{\delta}\bar{\phi} &= -2\big(\xi_1\eta_1 + \xi_2\eta_2\big). \end{aligned} \tag{6.18}$$

$$\begin{aligned} \hat{\delta}H &= 2\xi_2[\phi, \eta_1] - 2\xi_1[\phi, \eta_2] + 2\rho_1[\bar{\phi}, \chi_2] - 2\rho_2[\bar{\phi}, \chi_1] + 2[X_1, \rho_1\eta_1 - \rho_2\eta_2] \\ &+ 2[-\rho_1\eta_2 - \rho_2\eta_1, X_2]. \end{aligned} \tag{6.19}$$

For fermion fields we obtain $(\delta\theta_1)_R = -\hat{\delta}\eta_1$, $(\delta\theta_1)_I = \hat{\delta}\eta_2$, $(\delta\theta_2)_R = -\hat{\delta}\chi_2$ and $(\delta\theta_2)_I = \hat{\delta}\chi_1$. Another long calculation yields

$$\begin{aligned} -\hat{\delta}\eta_1 &= 2\xi_1[\phi, \bar{\phi}] - 2\xi_2 H - 2i\rho_1[X_1, \bar{\phi}] - 2i\rho_2[X_2, \bar{\phi}] \\ \hat{\delta}\eta_2 &= -2\xi_2[\phi, \bar{\phi}] - 2\xi_1 H - 2i\rho_2[X_1, \bar{\phi}] + 2i\rho_1[X_2, \bar{\phi}]. \end{aligned} \tag{6.20}$$

$$
\begin{aligned}
-\hat{\delta}\chi_2 &= -2\rho_2[\phi,\bar{\phi}] - 2\rho_1 H - 2i\rho_2[X_1,X_2] + 2\xi_1[X_1,\phi] + 2\xi_2[X_2,\phi] \\
\hat{\delta}\chi_1 &= 2\rho_1[\phi,\bar{\phi}] - 2\rho_2 H + 2i\rho_1[X_1,X_2] - 2\xi_2[X_1,\phi] + 2\xi_1[X_2,\phi]. \qquad (6.21)
\end{aligned}
$$

We look at the supercharge associated with ξ_2. We define the exterior derivative d on bosons by $dB = i[Q_{1R}, B]$ and on fermions by $dF = i\{Q_{1R}, F\}$, i.e $\hat{\delta}B = 2\xi_2 dB$ and $\hat{\delta}F = 2\xi_2 dF$. The corresponding supersymmetric transformations are

$$dX_i = \chi_i. \qquad (6.22)$$

$$d\phi = 0 \ , \ d\bar{\phi} = -\eta_2. \qquad (6.23)$$

$$dH = [\phi, \eta_1]. \qquad (6.24)$$

$$d\eta_1 = H \ , \ d\eta_2 = [\bar{\phi}, \phi]. \qquad (6.25)$$

$$d\chi_i = [\phi, X_i]. \qquad (6.26)$$

From these transformation laws we can immediately deduce that for any operator $\mathcal{O}$ we must have

$$d^2\mathcal{O} = [\phi, \mathcal{O}]. \qquad (6.27)$$

Thus d^2 is a gauge transformation generated by ϕ and as a consequence it is nilpotent on gauge invariant quantities such as the action.

Next we compute

$$\hat{\delta}\Big(-Tr\chi_i[X_i,\bar{\phi}]\Big) = 2\xi_2 Tr\Big([X_i,\phi][X_i,\bar{\phi}] - \chi_i[\bar{\phi},\chi_i] + \eta_2[\chi_i,X_i]\Big). \qquad (6.28)$$

$$\hat{\delta}\Big(Tr\eta_1[X_1,X_2]\Big) = 2\xi_2 Tr\Big(H[X_1,X_2] - \eta_1\epsilon_{ij}[\chi_i,X_j]\Big). \qquad (6.29)$$

$$\hat{\delta}\Big(Tr\eta_1 H\Big) = 2\xi_2 Tr\Big(H^2 - \eta_1[\phi,\eta_1]\Big). \qquad (6.30)$$

$$\hat{\delta}\Big(-Tr\eta_2[\phi,\bar{\phi}]\Big) = 2\xi_2 Tr\Big([\phi,\bar{\phi}]^2 - \eta_2[\phi,\eta_2]\Big). \qquad (6.31)$$

Hence

$$\hat{\delta}TrQ = 2\xi_2 S_{\rm cohom}. \qquad (6.32)$$

$$Q = -\chi_i[X_i,\bar{\phi}] + \eta_1[X_1,X_2] + \eta_1 H - \eta_2[\phi,\bar{\phi}]. \qquad (6.33)$$

As a consequence

$$dTrQ = S_{\rm cohom}. \qquad (6.34)$$

Thus we have

$$d^2TrQ = dS_{\rm cohom} = 0. \qquad (6.35)$$

In the above equation we have used the result $dS_{\rm cohom} = 0$. Thus d is nilpotent on gauge invariant quantities such as Q which are formed from traces. The term cohomology comes precisely from the analogy of d with an exterior derivative.

6.2 Cohomologically Deformed Supersymmetry

We consider the deformed action and deformed exterior derivative given by

$$S_{\rm def} = S_{\rm cohom} + \hat{S} = S_{\rm cohom} + \epsilon_1 S_1 + \epsilon_2 S_2 + ... \tag{6.36}$$

$$d_{\rm def} = d + \epsilon T. \tag{6.37}$$

Supersymmetric invariance requires

$$d_{\rm def} S_{\rm def} = 0. \tag{6.38}$$

The fact that d^2 is equal 0 on gauge invariant quantities, i.e. $d^2 S_{\rm cohom} = d^2 S_i = 0$ leads to $d^2 S_{\rm def} = 0$. We have the identity

$$d_{\rm def}^2 S_{\rm def} = 0. \tag{6.39}$$

This is equivalent to

$$\{d, T\} S_{\rm cohom} + \epsilon T^2 S_{\rm cohom} + \epsilon \{d, T\} \hat{S} + \epsilon T^2 \hat{S} = 0. \tag{6.40}$$

Thus we must have among other things

$$\{d, T\} S_{\rm cohom} = \{d, T\} \hat{S} = 0. \tag{6.41}$$

In other words $\{d, T\}$ generates one of the continuous bosonic symmetries of the action $S_{\rm def}$ which are gauge transformations and the remaining rotations given by the $SO(2)$ subgroup of $SO(4)$. Following [34] we choose $\{d, T\}$ to be the rotation U defined by

$$U : X_a \longrightarrow i\epsilon_{ab} X_b \ , \ \chi_a \longrightarrow i\epsilon_{ab}\chi_b. \tag{6.42}$$

We have then

$$\{d, T\} = U. \tag{6.43}$$

The symmetry T must also satisfy

$$T^2 = 0. \tag{6.44}$$

By following the method of [48] we can determine precisely the form of the correction T from the two requirements $T^2 = 0$ and $\{d, T\} = U$ and also from the assumption that T is linear in the fields. A straightforward calculation shows that there are two solutions but we will only consider here the one which generates mass terms for all the bosonic fields. This is given explicitly by

$$\begin{aligned} &TX_i = 0 \ , \ T\chi_i = i\epsilon_{ij} X_j \ , \ T\phi = 0 \\ &TH = i\gamma\eta_2 \ , \ T\eta_2 = 0 \ , \ T\eta_1 = -i\lambda\phi + i\gamma\bar{\phi} \ , \ T\bar{\phi} = 0. \end{aligned} \tag{6.45}$$

The cohomologically deformed supersymmetric transformations are therefore given by

$$d_{\rm def} X_i = \chi_i. \tag{6.46}$$

$$d_{\rm def}\phi = 0 \ , \ d_{\rm def}\bar{\phi} = -\eta_2. \tag{6.47}$$

$$d_{\rm def} H \ = \ [\phi, \eta_1] + i\epsilon\gamma\eta_2. \tag{6.48}$$

$$d_{\rm def}\eta_1 = H + \epsilon(-i\lambda\phi + i\gamma\bar{\phi}) \ , \ d_{\rm def}\eta_2 = [\bar{\phi}, \phi]. \tag{6.49}$$

$$d_{\rm def}\chi_i \ = \ [\phi, X_i] + i\epsilon\epsilon_{ij}X_j. \tag{6.50}$$

Furthermore we have the result

$$d^2_{\rm def} = d^2 + \epsilon U. \tag{6.51}$$

On $U-$invariant quantities we have $d^2_{\rm def} = d^2$. For example $d^2_{\rm def} = d^2$ on quantities independent of X_a and χ_a. Also $d^2_{\rm def}(\chi_a X_a) = d^2(\chi_a X_a)$ and $d^2_{\rm def}(\epsilon^{ab}\chi_a X_b) = d^2(\epsilon^{ab}\chi_a X_b)$. Thus we have on $U-$invariant quantities the identity

$$d^2_{\rm def}(...) = d^2(...) = [\phi, ...]. \tag{6.52}$$

6.3 Cohomologically Deformed Action

Next we need to solve the condition (6.38). The deformed action is a trace over some polynomial P. In the non-deformed case we have $S = dQ$ where Q is a $U-$invariant expression given by (6.33). We assume that the deformed action $S_{\rm def} = TrP$ is also $U-$invariant. By using the theorem of Austing [48] we can conclude that the general solution of the condition (6.38), or equivalently of the equation $d_{\rm def}TrP = 0$, is

$$S_{\rm def} = d_{\rm def}TrQ_{\rm def} + TrR_3(\phi). \tag{6.53}$$

For $SU(N)$ gauge group this result holds as long as the degree of P is less than $2N/3$. Clearly when the deformation is sent to zero $d_{\rm def} \longrightarrow d$, $Q_{\rm def} \longrightarrow Q$ and $R \longrightarrow 0$. Thus we take

$$Q_{\rm def} = Q - iR \ , \ R = \kappa_1 R_1 + \kappa_2 R_2. \tag{6.54}$$

We choose R_1 and R_2 to be the $U-$invariant quantities given by

$$R_1 = \frac{1}{2}\epsilon_{ab}\chi_a X_b \ , \ R_2 = -\eta_1\bar{\phi}. \tag{6.55}$$

We choose $R_3(\phi)$ to be the $U-$invariant quantity given by

$$R_3(\phi) = -\rho^2\phi^2. \tag{6.56}$$

In order to remove the deformation we must take $\epsilon \longrightarrow 0$ so that $d_{\rm def} \longrightarrow d$ and $\rho \longrightarrow 0$ so that $S_{\rm def} \longrightarrow dTrQ_{\rm def}$ and $\kappa_i \longrightarrow 0$ so that $Q_{\rm def} \longrightarrow Q$.

We compute

$$\begin{aligned} S_{\rm def} &= dTrQ - idTrR + \epsilon TTrQ - i\epsilon TTrR + TrR_3(\phi) \\ &= S_{\rm cohom} + \hat{S}. \end{aligned} \tag{6.57}$$

The first term $S_{\rm cohom} = dTrQ$ is the original action. By using the result that $d(F_1F_2) = dF_1.F_2 - F_1dF_2$ and $T(F_1F_2) = TF_1.F_2 - F_1TF_2$ we obtain

$$-idTrR = -iTr\Big[\kappa_1\phi[X_1,X_2] - \kappa_1\chi_1\chi_2 - \kappa_2 H\bar{\phi} - \kappa_2\eta_1\eta_2\Big]. \tag{6.58}$$

$$\epsilon TTrQ = \epsilon Tr\Big[-i\lambda\phi(H + [X_1,X_2]) + i\gamma\bar{\phi}H - i\gamma\eta_1\eta_2 + i(\gamma+2)\bar{\phi}[X_1,X_2]\Big]. \tag{6.59}$$

$$-i\epsilon TTrR = \epsilon Tr\Big(\frac{1}{2}\kappa_1 X_i^2 + \kappa_2\lambda\phi\bar{\phi} - \kappa_2\gamma\bar{\phi}^2\Big). \tag{6.60}$$

Also

$$TrR_3(\phi) = Tr(-\rho^2\phi^2). \tag{6.61}$$

We will choose the parameters so that the total action enjoys $SO(3)$ covariance with a Myers (Chern-Simons) term and mass terms for all the bosonic and fermionic matrices. The relevant fermionic terms are

$$i\kappa_1 Tr(\chi_1\chi_2 - \eta_1\eta_2) + i(\kappa_1 + \kappa_2 - \epsilon\gamma)Tr\eta_1\eta_2 = i\kappa_1 Tr(\chi_1\chi_2 - \eta_1\eta_2). \tag{6.62}$$

For $SO(3)$ covariance we have chosen

$$\kappa_1 + \kappa_2 - \epsilon\gamma = 0. \tag{6.63}$$

Next we remark

$$\begin{aligned} &Tr\Big(H^2 + H[X_1,X_2]\Big) + i(\kappa_2+\epsilon\gamma)TrH\bar{\phi} - i\epsilon\lambda TrH\phi \;\; = \\ &Tr\Big(H + \frac{1}{2}[X_1,X_2] + \frac{i}{2}(\kappa_2+\epsilon\gamma)\bar{\phi} - \frac{i}{2}\epsilon\lambda\phi\Big)^2 - \frac{1}{4}Tr[X_1,X_2]^2 \;\; + \\ &\frac{1}{4}Tr\Big((\kappa_2+\epsilon\gamma)\bar{\phi} - \epsilon\lambda\phi\Big)^2 - \frac{i}{2}Tr\Big((\kappa_2+\epsilon\gamma)\bar{\phi} - \epsilon\lambda\phi\Big)[X_1,X_2]. \end{aligned} \tag{6.64}$$

The relevant bosonic mass terms are therefore given by

$$\begin{aligned} &Tr\Big(\frac{1}{2}\epsilon\kappa_1 X_i^2 + \epsilon\kappa_2\lambda\phi\bar{\phi} - \epsilon\kappa_2\gamma\bar{\phi}^2 - \rho^2\phi^2\Big) + \frac{1}{4}Tr\Big((\kappa_2+\epsilon\gamma)\bar{\phi} - \epsilon\lambda\phi\Big)^2 \;\; = \\ &\frac{1}{2}\epsilon\kappa_1 TrX_i^2 + (\frac{1}{4}\epsilon^2\lambda^2 - \rho^2)Tr\phi^2 + \frac{1}{4}(\kappa_2-\epsilon\gamma)^2 Tr\bar{\phi}^2 + \frac{1}{2}\epsilon\lambda(\kappa_2-\epsilon\gamma)Tr\phi\bar{\phi}. \end{aligned} \tag{6.65}$$

In order to cancel the cross product we choose

$$\frac{1}{4}\epsilon^2\lambda^2 - \rho^2 = \frac{1}{4}(\kappa_2 - \epsilon\gamma)^2. \tag{6.66}$$

Then

$$\begin{aligned} Tr\Big(\frac{1}{2}\epsilon\kappa_1 X_i^2 + \epsilon\kappa_2\lambda\phi\bar{\phi} - \epsilon\kappa_2\gamma\bar{\phi}^2 - \rho^2\phi^2\Big) + \frac{1}{4}Tr\Big((\kappa_2+\epsilon\gamma)\bar{\phi} - \epsilon\lambda\phi\Big)^2 &= \\ \frac{1}{2}\epsilon\kappa_1 TrX_i^2 + \frac{1}{8}(\kappa_2-\epsilon\gamma)(\kappa_2-\epsilon\gamma-\epsilon\lambda)TrX_3^2 - \frac{1}{8}(\kappa_2-\epsilon\gamma)(\kappa_2-\epsilon\gamma+\epsilon\lambda)TrX_4^2 &= \\ \frac{1}{2}\epsilon\kappa_1 TrX_a^2 - \frac{1}{8}(\kappa_2-\epsilon\gamma)(\kappa_2-\epsilon\gamma+\epsilon\lambda)TrX_4^2. \end{aligned} \tag{6.67}$$

Again for $SO(3)$ covariance we have chosen

$$\frac{1}{2}\epsilon\kappa_1 = \frac{1}{8}(\kappa_2-\epsilon\gamma)(\kappa_2-\epsilon\gamma-\epsilon\lambda). \tag{6.68}$$

The Chern-Simons term can be obtained from the terms

$$\begin{aligned} Tr\Big(-i(\kappa_1+\epsilon\lambda)\phi[X_1,X_2] + i\epsilon(\gamma+2)\bar{\phi}[X_1,X_2]\Big) - \frac{i}{2}Tr\Big((\kappa_2+\epsilon\gamma)\bar{\phi} - \epsilon\lambda\phi\Big)[X_1,X_2] &= \\ -\frac{i}{2}(\epsilon\lambda+2\kappa_1)Tr\phi[X_1,X_2] + \frac{i}{2}(-\kappa_2+\epsilon\gamma+4\epsilon)Tr\bar{\phi}[X_1,X_2] &= \\ -\frac{i}{4}(\epsilon\lambda+\epsilon\gamma+2\kappa_1-\kappa_2+4\epsilon)TrX_3[X_1,X_2] + \frac{1}{4}(\epsilon\lambda-\epsilon\gamma+2\kappa_1+\kappa_2-4\epsilon)TrX_4[X_1,X_2]. \end{aligned} \tag{6.69}$$

The first term is the Chern-Simons action. We want to impose the condition

$$\epsilon\lambda + 2\kappa_1 + \kappa_2 = \epsilon\gamma + 4\epsilon. \tag{6.70}$$

The solution of equations (6.63), (6.66), (6.68) and (6.70) is

$$\gamma = \frac{\kappa_1+\kappa_2}{\epsilon}\ ,\ \lambda = 4 - \frac{\kappa_1}{\epsilon}\ ,\ \rho^2 = 2\epsilon(2\epsilon-\kappa_1). \tag{6.71}$$

The deformation action $\Delta S_{\rm cohom}$ is therefore

$$\begin{aligned} \Delta S_{\rm cohom} &= i\kappa_1 Tr(\chi_1\chi_2 - \eta_1\eta_2) + \frac{1}{2}\epsilon\kappa_1 TrX_a^2 - \frac{1}{8}(\kappa_2-\epsilon\gamma)(\kappa_2-\epsilon\gamma+\epsilon\lambda)TrX_4^2 \\ &- \frac{i}{4}(\epsilon\lambda+\epsilon\gamma+2\kappa_1-\kappa_2+4\epsilon)TrX_3[X_1,X_2] \\ &= \frac{\kappa_1}{2}Tr\theta^+\theta + \frac{1}{2}\epsilon\kappa_1 TrX_a^2 + \frac{1}{4}\kappa_1(2\epsilon-\kappa_1)TrX_4^2 - \frac{i}{6}(4\epsilon+\kappa_1)\epsilon_{abc}TrX_aX_bX_c. \end{aligned} \tag{6.72}$$

We introduce now

$$-(4\epsilon+\kappa_1) = \alpha\ ,\ \kappa_1 = -\frac{\alpha}{3} + 4\zeta_0\alpha. \tag{6.73}$$

Thus we get

$$\begin{aligned} \Delta S_{\rm cohom} &= -\frac{\alpha}{6}(1-12\zeta_0)Tr\theta^+\theta + \frac{\alpha^2}{36}(1+6\zeta_0)(1-12\zeta_0)TrX_a^2 + \frac{\alpha^2}{2}\zeta_0(1-12\zeta_0)TrX_4^2 \\ &+ \frac{i}{6}\alpha\epsilon_{abc}TrX_aX_bX_c. \end{aligned} \tag{6.74}$$

The total action is

$$\begin{aligned} S_{\rm def} &= \Big(S_{\rm cohom} - Tr(H^2 + H[X_1, X_2])\Big) + Tr\Big(H + \frac{1}{2}[X_1, X_2] + \frac{i}{2}(\kappa_2 + \epsilon\gamma)\bar{\phi} - \frac{i}{2}\epsilon\lambda\phi\Big)^2 \\ &- \frac{1}{4}Tr[X_1, X_2]^2 + \Delta S_{\rm cohom}. \end{aligned} \tag{6.75}$$

The first line is effectively equivalent to $S_{\rm cohom}$. Thus the total action is

$$S_{\rm def} = S_{\rm cohom} + \Delta S_{\rm cohom}. \tag{6.76}$$

Next we perform the scaling

$$X_\mu \longrightarrow (2N)^{\frac{1}{4}} X_\mu \ , \ \theta \longrightarrow \sqrt{\frac{2}{N\alpha}} \frac{1}{(2N)^{\frac{1}{8}}}\theta, \tag{6.77}$$

and

$$\alpha \longrightarrow 2(2N)^{\frac{1}{4}}\alpha. \tag{6.78}$$

We get then the one-parameter family of actions given by (we set $B = 0$)

$$\begin{aligned} S_{\rm def} &= -\frac{N}{4}Tr[X_\mu, X_\nu]^2 + N\frac{2i\alpha}{3}\epsilon_{abc}TrX_aX_bX_c + \frac{2N\alpha^2}{9}(1 + 6\zeta_0)(1 - 12\zeta_0)TrX_a^2 \\ &+ 4N\alpha^2\zeta_0(1 - 12\zeta_0)TrX_4^2 - \frac{1}{N\alpha}Tr\theta^+\Big(i[X_4, ..] + \sigma_a[X_a, ..] + \frac{2\alpha}{3}(1 - 12\zeta_0)\Big)\theta. \end{aligned} \tag{6.79}$$

For stability the parameter ζ_0 must be in the range

$$0 < \zeta_0 < 1/12. \tag{6.80}$$

This action for $\zeta_0 = 0$ is precisely the mass deformed action derived in section 2. The value $\zeta_0 = 1/12$ will also be of interest to us in this article. This one-parameter family of actions preserves only half of the $\mathcal{N} = 1$ supersymmetry in the sense that we can construct only two mass deformed supercharges [48].

7 Simulation Results for $D = 4$ Yang-Mills Matrix Models

7.1 Models, Supersymmetry and Fuzzy Sphere

We are interested in the cohomologically deformed Yang-Mills matrix models

$$\begin{aligned} S &= NTr\Big[-\frac{1}{4}[X_\mu, X_\nu]^2 + \frac{2i\alpha}{3}\epsilon_{abc}X_aX_bX_c\Big] + N\beta TrX_a^2 + N\beta_4 TrX_4^2 \\ &- \frac{1}{N\alpha}Tr\theta^+\Big(i[X_4, ..] + \sigma_a[X_a, ..] + \zeta\Big)\theta. \end{aligned} \tag{7.1}$$

The range of the parameters is

$$\beta = \frac{2}{9}(\alpha + 6\xi_0)(\alpha - 12\xi_0) \ , \ \beta_4 = 4\xi_0(\alpha - 12\xi_0) \ , \ \zeta = \frac{2}{3}(\alpha - 12\xi_0). \tag{7.2}$$

$$0 \leq \xi_0 \leq \frac{\alpha}{12}. \tag{7.3}$$

This action preserves two supercharges compared to the four supercharges of the original non deformed Yang-Mills matrix model [48]. We will be mainly interested in the "minimally" deformed Yang-Mills matrix model corresponding to the value $\xi_0 = \alpha/12$ for which we have

$$S = NTr\bigg[-\frac{1}{4}[X_\mu, X_\nu]^2 + \frac{2i\alpha}{3}\epsilon_{abc}X_aX_bX_c\bigg] - \frac{1}{N\alpha}Tr\theta^+\bigg(i[X_4,..] + \sigma_a[X_a,..]\bigg)\theta. \tag{7.4}$$

The "maximally" deformed Yang-Mills matrix model corresponding to the value $\xi_0 = 0$ coincides precisely with the mass-deformed model in $D = 4$ and as such it has a full $\mathcal{N} = 1$ mass deformed supersymmetry besides the half $\mathcal{N} = 1$ cohomologically deformed supersymmetry. From this perspective this case is far more important than the previous one. However there is the issue of the convergence of the partition function which we will discuss shortly. In any case the "maximally" deformed Yang-Mills matrix model is given by the action

$$\begin{aligned} S &= NTr\bigg[-\frac{1}{4}[X_\mu, X_\nu]^2 + \frac{2i\alpha}{3}\epsilon_{abc}X_aX_bX_c\bigg] + N\frac{2\alpha^2}{9}TrX_a^2 \\ &- \frac{1}{N\alpha}Tr\theta^+\bigg(i[X_4,..] + \sigma_a[X_a,..] + \frac{2}{3}\alpha\bigg)\theta. \end{aligned} \tag{7.5}$$

The above two actions can also be rewritten as (with $X_a = \alpha D_a$ and $\tilde{\alpha} = \alpha\sqrt{N}$)

$$\begin{aligned} S_{\text{SUSY}} &= NTr\bigg[-\frac{1}{4}[X_a, X_b]^2 + \frac{2i\alpha}{3}\epsilon_{abc}X_aX_bX_c\bigg] + N\tilde{\beta}\alpha^2TrX_a^2 \\ &- \frac{1}{N\alpha}Tr\theta^+\bigg(i[X_4,..] + \sigma_a[X_a,..] + \alpha\tilde{\xi}\bigg)\theta. \end{aligned} \tag{7.6}$$

Equivalently

$$\begin{aligned} S_{\text{SUSY}} &= \frac{\tilde{\alpha}^4}{N}Tr\bigg[-\frac{1}{4}[D_a, D_b]^2 + \frac{2i}{3}\epsilon_{abc}D_aD_bD_c\bigg] + \frac{\tilde{\beta}\tilde{\alpha}^4}{N}TrD_a^2 \\ &- \frac{1}{N}Tr\theta^+\bigg(i[D_4,..] + \sigma_a[D_a,..] + \tilde{\xi}\bigg)\theta. \end{aligned} \tag{7.7}$$

$$\begin{aligned} &\tilde{\beta} = 0 \ , \ \tilde{\xi} = 0 \ \text{ cohomologically deformed} \\ &\tilde{\beta} = \frac{2}{9} \ , \ \tilde{\xi} = \frac{2}{3} \ \text{ mass deformed.} \end{aligned} \tag{7.8}$$

We remark that the bosonic part of the mass-deformed Yang-Mills matrix action can be rewritten as a complete square, viz

$$\begin{aligned} S_B &= NTr\Big[-\frac{1}{4}[X_\mu, X_\nu]^2 + \frac{2i\alpha}{3}\epsilon_{abc}X_aX_bX_c\Big] + N\frac{2\alpha^2}{9}TrX_a^2 \\ &= NTr\bigg(\frac{i}{2}[X_\mu, X_\nu] + \frac{\alpha}{3}\epsilon_{\mu\nu\lambda}X_\lambda\bigg)^2. \end{aligned} \tag{7.9}$$

Clearly $\epsilon_{\mu\nu\lambda} = 0$ if any of the indices μ,ν,λ takes the value 4. Generically the bosonic action of interest is given by

$$S_B = NTr\Big[-\frac{1}{4}[X_\mu, X_\nu]^2 + \frac{2i\alpha}{3}\epsilon_{abc}X_aX_bX_c\Big] + N\tilde{\beta}\alpha^2TrX_a^2. \tag{7.10}$$

Here we allow $\tilde{\beta}$ to take on any value. The variation of the bosonic action for generic values of $\tilde{\beta}$ reads

$$\begin{aligned} &\delta S_B = NTrJ_4\delta X_4 + NTrJ_b\delta X_b \\ &J_4 = [X_a, [X_a, X_4]]\ ,\ J_b = 2\tilde{\beta}\alpha^2X_b + i[F_{ab}, X_a] + [X_4, [X_4, X_b]]\ , \\ &F_{ab} = i[X_a, X_b] + \alpha\epsilon_{abc}X_c. \end{aligned} \tag{7.11}$$

Thus extrema of the model are given by 1) reducible representations J_a of $SU(2)$, i.e $X_a = J_a$ and $X_4 = 0$ and 2) commuting matrices, i.e X_μ belong to the Cartan subalgebra of $SU(N)$. The identity matrix corresponds to an uncoupled mode and thus we have $SU(N)$ instead of $U(N)$. Global minima are given by irreducible representations of $SU(2)$ of dimensions N and 0. Indeed we find that the configurations $X_a = \phi L_a$, $X_4 = 0$ solve the equations of motion with ϕ satisfying the cubic equation $\phi(\phi^2 - \alpha\phi + \tilde{\beta}\alpha^2) = 0$. We get the solutions

$$\phi_0 = 0\ ,\ \phi_\pm = \alpha\frac{1 \pm \sqrt{1 - 4\tilde{\beta}}}{2}. \tag{7.12}$$

We can immediately see that we must have $\tilde{\beta}\leq 1/4$ which does indeed hold for the values of interest $\tilde{\beta} = 0$ and $\tilde{\beta} = 2/9$. However the action at $\phi_\pm$ is given by

$$S_B[\phi_\pm] = \frac{N^2c_2\phi_\pm^2}{2}\alpha^2\bigg(\tilde{\beta} - \frac{1}{6} \mp \frac{1}{6}\sqrt{1 - 4\tilde{\beta}}\bigg). \tag{7.13}$$

We can verify that $S_B[\phi_-]$ is always positive while $S_B[\phi_+]$ is negative for the values of $\tilde{\beta}$ such that $\tilde{\beta}\leq 2/9$. Furthermore we note that $S[\phi_0] = 0$. In other words for $\tilde{\beta}\leq 2/9$ the global minimum of the model is the irreducible representation of $SU(2)$ of maximum dimension N whereas for $\tilde{\beta} > 2/9$ the global minimum of the model is the irreducible representation of $SU(2)$ of minimum dimension 0.

At $\tilde{\beta} = 2/9$ we get $\phi_+ = 2\alpha/3$ and $S[\phi_+] = 0$. Thus the configuration $X_a = \frac{2\alpha}{3}L_a$ becomes degenerate with the configuration $X_a = 0$. However there is an entire $SU(N)$ manifold of configurations $X_a = \frac{2\alpha}{3}UL_aU^+$ which are equivalent to the fuzzy sphere configuration. In other words the fuzzy sphere configuration is still favored although now

due to entropy. Thus there is a first order transition at $\tilde{\beta} = 2/9$ when the classical ground state switches from $X_a = \frac{2}{3}L_a$ to $X_a = 0$ as we increase $\tilde{\beta}$ through the critical value $\tilde{\beta} = 2/9$. The two values of interest $\tilde{\beta} = 0$ and $\tilde{\beta} = 2/9$ both lie in the regime where the fuzzy sphere is the stable classical ground state.

This discussion holds also for the full bosonic model in which we include a mass term for the matrix X_4. Quantum correction, i.e. the inclusion of fermions, are expected to alter significantly this picture.

Towards the commutative limit we rewrite the action, the second line of (7.7), into the form (with $\tilde{\alpha}^4 = 1/g^2$ and $F_{ab} = i[D_a, D_b] + \epsilon_{abc}\phi D_c$)

$$\begin{aligned} S &= \frac{1}{4g^2N}TrF_{ab}^2 - \frac{3\phi-2}{6g^2N}Tr\left[\epsilon_{abc}F_{ab}D_c + \phi D_a^2\right] + \frac{1}{g^2N}\Big(\phi(\phi-1) + \tilde{\beta}\Big)TrD_a^2 \\ &- \frac{1}{2g^2N}Tr[D_a, D_4]^2 - \frac{1}{N}Tr\theta^+\big(i[D_4, ..] + \sigma_a[D_a, ..] + \tilde{\xi}\big)\theta. \end{aligned} \tag{7.14}$$

The 3rd terms actually cancel for all values of β. Thus

$$\begin{aligned} S &= \frac{1}{4g^2N}TrF_{ab}^2 - \frac{3\phi-2}{6g^2N}Tr\left[\epsilon_{abc}F_{ab}D_c + \phi D_a^2\right] - \frac{1}{2g^2N}Tr[D_a, D_4]^2 \\ &- \frac{1}{N}Tr\theta^+\big(i[D_4, ..] + \sigma_a[D_a, ..] + \tilde{\xi}\big)\theta. \end{aligned} \tag{7.15}$$

The commutative limit $N \longrightarrow \infty$ is then obvious. We write $D_a = \phi(L_a + A_a)$ and we obtain

$$S = \frac{1}{4g^2}\int_{S^2} F_{ab}^2 - \frac{(3\phi-2)\phi}{4g^2}\epsilon_{abc}\int F_{ab}A_c - \frac{1}{2g^2}\int_{S^2}(\mathcal{L}_a D_4)^2 - \int_{S^2}\psi^+\big(\phi\sigma_a\mathcal{L}_a + \tilde{\xi}\big)\psi. \tag{7.16}$$

7.2 Path Integral, Convergence and Observables

In the quantum theory we will integrate over $N \times N$ bosonic matrices X_μ and $N \times N$ fermionic matrices θ_α^+ and θ_α. The trace parts of X_μ, θ_α^+ and θ_α will be removed since they correspond to free degrees of freedom. The partition function of the model is therefore given by

$$\begin{aligned} Z &= \int \mathcal{D}X_\mu\ \mathcal{D}\theta\ \mathcal{D}\theta^+\ \delta\big(TrX_\mu\big)\ \delta\big(Tr\theta_\alpha^+\big)\ \delta\big(Tr\theta_\alpha\big)\ e^{-S_{\rm SUSY}} \\ &= \int \mathcal{D}X_\mu \delta\ \big(TrX_\mu\big)\ \mathrm{det}\mathcal{D}\ e^{-S_B}. \end{aligned} \tag{7.17}$$

$$\mathrm{det}\mathcal{D} = \int d\theta d\theta^+ \delta(Tr\theta_\alpha)\delta(Tr\theta_\alpha^+)e^{\frac{1}{N\alpha}Tr\theta^+\mathcal{D}\theta}. \tag{7.18}$$

The integration over the fermions yielded the determinant of the $2(N^2-1) \times 2(N^2-1)$ dimensional matrix $\mathcal{D} = i[X_4, ..] + \sigma_a[X_a, ..] + \tilde{\xi}\alpha$. This determinant is positive definite since every eigenvalue λ of $\mathcal{D}$ is doubly degenerate [46]. The reason lies in the fact that

the Dirac operator $\mathcal{D} = iX_4 - iX_4^R + \sigma_a X_a - \sigma_a X_a^R + \tilde{\xi}\alpha$ is symmetric under the exchange of left and right operators, viz under $X_a \leftrightarrow -X_a^R$. A much cleaner proof goes as follows. Let Ψ be an eigenstate of $\mathcal{D}$ with eigenvalue λ, in other words

$$i[X_4, \Psi] + \sigma_a[X_a, \Psi] + \tilde{\xi}\alpha\psi = \lambda\Psi. \tag{7.19}$$

Taking the hermitian conjugate of this equation we get

$$i[X_4, (\Psi^+)^T] - \sigma_a^T[X_a, (\Psi^+)^T] + \tilde{\xi}\alpha(\Psi^+)^T = \lambda(\Psi^+)^T. \tag{7.20}$$

In above $(\Psi^+)^T$ is a column vector with components given by $\Psi^+_{1,2}$. Multiplying the above equation by σ_2 and defining the spinor $\tilde{\Psi} = \sigma_2(\Psi^+)^T$ we arrive at the equation

$$i[X_4, \tilde{\Psi}] + \sigma_a[X_a, \tilde{\Psi}] + \xi\alpha\tilde{\Psi} = \lambda\tilde{\Psi}. \tag{7.21}$$

We have also used the identity $\sigma_a = -\sigma_2\sigma_a^T\sigma_2$. We conclude that $\tilde{\Psi}$ is also an eigenstate of $\mathcal{D}$ with the same eigenvalue λ. The spinors Ψ and $\tilde{\Psi}$ are charge conjugate to each other. In above we have assumed that λ is real which follows from the fact that the Dirac operator $\mathcal{D} = i[X_4, ..] + \sigma_a[X_a, ..] + \tilde{\xi}\alpha$ is hermitian. This establishes that the determinant $\det\mathcal{D}$ is positive definite for any configuration X_μ and hence the model can be accessed directly by Monte Carlo simulation.

Let us also add that the Dirac operator $\mathcal{D}$ admits an approximate chirality operator and hence there is an approximate chiral symmetry in this model beside exact rotational invariance, exact gauge invariance and exact charge conjugation. The existence of chiral symmetry (though approximate) means that there should exist more structure in the low energy fermionic spectrum.

The partition function Z is also invariant under the translation $X_\mu \longrightarrow X_\mu + \epsilon X_\mu$ where ϵ is a small parameter. Under this coordinate transformation the measure dX_μ changes to $(1 + 4(N^2-1)\epsilon)dX_\mu$. The bosonic action $S_B = S_4 + S_3 + S_2$ changes to $S_B + \epsilon(4S_4 + 3S_3 + 2S_2)$ under $X_\mu \longrightarrow X_\mu + \epsilon X_\mu$. The determinant, on the other hand, changes under $X_\mu \longrightarrow X_\mu + \epsilon X_\mu$ as

$$\begin{aligned} \det\mathcal{D} &\longrightarrow (1+\epsilon)^{2(N^2-1)}\det{}'\left(\mathcal{M}' - \epsilon\tilde{\xi}\alpha(1+\gamma)\right) \\ &\longrightarrow (1+\epsilon)^{2(N^2-1)}\det{}'\left(1 - \frac{\epsilon}{\mathcal{M}'}\tilde{\xi}\alpha(1+\gamma)\right)\det{}'\mathcal{M}'. \end{aligned} \tag{7.22}$$

The matrices $\mathcal{M}'$ and γ are given in appendix B. We obtain then

$$\det\mathcal{D} \longrightarrow \left(1 + \epsilon\left[2(N^2-1) - \tilde{\xi}\alpha Tr'_{\rm ad}\frac{1}{\mathcal{D}} - \tilde{\xi}\alpha Tr'_{\rm ad}\frac{1}{\mathcal{D}}\gamma\right]\right)\det\mathcal{D}. \tag{7.23}$$

From the invariance of the partition function under the coordinate transformation $X_\mu \longrightarrow X_\mu + \epsilon X_\mu$ we derive therefore the Schwinger-Dyson identity

$$\begin{aligned} \text{IDE} &= 4\frac{<\text{YM}>}{N^2} + 4\frac{<\text{YM}_0>}{N^2} + 3\frac{<\text{CS}>}{N^2} + 2\frac{<\text{RAD}>}{N^2} + \tilde{\xi}\alpha\frac{\text{COND}}{N^2} + \frac{6}{N^2} \\ &\equiv 6. \end{aligned} \tag{7.24}$$

This is an exact result.

The operators YM, YM_0 and CS are the actions given by

$$\mathrm{YM} = -\frac{N}{4} Tr[X_a, X_b]^2 \ , \ \mathrm{YM}_0 = -\frac{N}{2} Tr[X_0, X_a]^2 \ , \ \mathrm{CS} = \frac{iN\alpha}{3} \epsilon_{abc} Tr[X_a, X_b] X_c. \tag{7.25}$$

The action RAD is related to the radius of the sphere. It is given by

$$\mathrm{RAD} = N\tilde{\beta}\alpha^2 Tr X_a^2. \tag{7.26}$$

We will define the radius r of the sphere through the relation

$$\frac{1}{r} = \frac{1}{N\alpha^2 c_2} Tr X_a^2. \tag{7.27}$$

The total bosonic action is given by $S = \mathrm{YM} + \mathrm{YM}_0 + \mathrm{CS} + \mathrm{RAD}$. The condensation is defined by

$$\mathrm{COND} \ = \ \frac{1}{\alpha} \frac{\partial \ln Z}{\partial \tilde{\xi}} = < \frac{1}{N\alpha} Tr \theta^+ \theta > . \tag{7.28}$$

We find

$$\mathrm{COND} \ = \ \mathrm{COND}_0 + \mathrm{COND}_1. \tag{7.29}$$

$$\begin{aligned} \mathrm{COND}_0 &= < Tr_{\mathrm{ad}}^{'} \frac{1}{i[X_4, ..] + \sigma_a [X_a, ..] + \tilde{\xi}\alpha} >, \\ \mathrm{COND}_1 &= < Tr_{\mathrm{ad}}^{'} \frac{1}{i[X_4, ..] + \sigma_a [X_a, ..] + \tilde{\xi}\alpha} \gamma > . \end{aligned} \tag{7.30}$$

These are real quantities. The condensation COND_0 is obviously real since every eigenvalue of the Dirac operator is doubly degenerate. The expression of the total condensation COND suggests that it is real. We have verified numerically that COND_1 is real and that the condensation is dominated by COND_0.

For completeness we will also measure the logarithm of the determinant of the Dirac operator as an independent observable in Monte Carlo simulation.

Convergence of Yang-Mills path inetgrals such as the one given by (7.17) was studied extensively in [48] and in [49–54]. This question is of paramount importance for analytical analysis as well as for Monte Carlo simulation. The source of the divergence, if any lies in the so-called flat directions, i.e. the set of commuting matrices.

The path integral (7.17) corresponds to a gauge theory with gauge group $SU(N)$ in dimension $D = 4$. We will also consider $SU(N)$ gauge theory in dimension $D = 3$. We start the discussion with the model $\alpha = 0$, $\tilde{\beta} = 0$ and $\tilde{\xi} = 0$. It was found in [49] that the bosonic path integral in $D = 3$ is convergent for $N \geq 4$ while the bosonic path integral in $D = 4$ is convergent for $N \geq 3$. Since we are interested in large values of N we can safely consider the bosonic path integrals in $D = 3, 4$ to be convergent for all practical purposes. On the other hand, it is found in [53], that the supersymmetric path integral in $D = 3$

is not convergent while the supersymmetric path integral in $D = 4$ is convergent for all $N \geq 2$.

Tuning the parameters α, $\tilde{\beta}$ does not change this picture. For example it was shown in [54] that adding a Myers term, i.e. considering a non-zero value of α, does not change the convergence properties of the $D-$dimensional Yang-Mills matrix path integral. The point is that the Chern-Simons (Myers) term is always small compared to the quartic Yang-Mills term. The same argument should then lead to the conclusion that adding a bosonic mass term, i.e. if we consider a non-zero $\tilde{\beta}$, will not change the above picture.

Tuning the fermion mass term, i.e. considering a non-zero value of the scalar curvature $\tilde{\xi}$, will lead to complications. In this case the Pfaffian, or equivalently the determinant, will be expanded as a polynomial in the scalar curvature $\tilde{\xi}$. The analysis of [53] should then be repeated for every term in this expansion. We claim that the supersymmetric path integral in $D = 4$ is not convergent for generic values of $\tilde{\xi}$.

We have extensively checked in Monte Carlo simulation the conjecture that Yang-Mills matrix models in dimension $D = 4$ does not make sense for generic values of $\tilde{\xi}$. The major observation is that for $\tilde{\xi} \neq 0$ the fermion determinant for generic values of $\tilde{\alpha} = \sqrt{N}\alpha$ never reaches thermalization [2]. However, we have also observed that for sufficiently small values of $\tilde{\xi}$ the theory actually makes sense and thus there is some critical value of $\tilde{\xi}$, which we will not determine in this article, above which the path integral is ill defined. The value of interest $\tilde{\xi} = 2/3$ corresponding to the mass deformed matrix model lies in this range where the model is actually ill defined.

Therefore in order to access the mass deformed Yang-Mills matrix model by the Monte Carlo method we must regularize the theory in such a way as to make sure that the path integral is absolutely convergent. Unfortunately most regularizations will not maintain neither the full $\mathcal{N} = 1$ mass deformed supersymmetry nor the half $\mathcal{N} = 1$ cohomologically deformed supersymmetry of this model. We adopt here the regularization in which we will simply set $\tilde{\xi} = 0$. In other words we make the replacement

$$\begin{aligned} S_{\rm SUSY} \longrightarrow S'_{\rm SUSY} &= NTr\Big[-\frac{1}{4}[X_a, X_b]^2 + \frac{2i\alpha}{3}\epsilon_{abc}X_aX_bX_c\Big] + N\tilde{\beta}\alpha^2 TrX_a^2 \\ &- \frac{1}{N\alpha}Tr\theta^+\Big(i[X_4, ..] + \sigma_a[X_a, ..]\Big). \end{aligned} \tag{7.31}$$

In summary, the value $\tilde{\beta} = 2/9$ corresponds to the mass deformed Yang-Mills matrix model with softly broken supersymmetry whereas the value $\tilde{\beta} = 0$ is precisely the minimally deformed model which enjoys half of the $\mathcal{N} = 1$ cohomologically deformed supersymmetry.

The Metropolis algorithm and other algorithms used to study these models numerically and the detail of the simulations can be found in appendices A and B.

[2] This happens typically for small values of $\tilde{\alpha}$ far from the fuzzy sphere region but not very close to $\tilde{\alpha} = 0$.

7.3 Bosonic Theory: Emergent Geometry and Phase Diagram

Emergent Geometry We measure the different observables as a function of the coupling constant $\tilde{\alpha}$ for the two relevant values of $\tilde{\beta}$, i.e. $\tilde{\beta} = 0, 2/9$. We have verified that the bosonic Schwinger-Dyson equation holds in Monte Carlo simulations. See figure (12). Recall that this identity reads for the bosonic models as follows

$$\text{IDE} \;=\; 4\frac{< \text{YM} >}{N^2} + 4\frac{< \text{YM}_0 >}{N^2} + 3\frac{< \text{CS} >}{N^2} + 2\frac{< \text{RAD} >}{N^2} + \frac{4}{N^2} \equiv 4. \quad (7.32)$$

The radius which we have defined by the equation $< 1/r >=< TrX_a^2 > /\tilde{\alpha}^2 c_2$ is shown on figure (7). For large values of $\tilde{\alpha}$ the result is consistent with the classical prediction

$$< \frac{1}{r} >=< \frac{TrX_a^2}{\tilde{\alpha}^2 c_2} >= \phi_+^2 \ , \ \phi_+ = \frac{1+\sqrt{1-4\tilde{\beta}}}{2}. \quad (7.33)$$

This means in particular that the system is in the ground state configurations

$$X_4 = 0 \ , \ X_a = \alpha\phi L_a. \quad (7.34)$$

In other words we have a fuzzy spherical geometry given by the commutation relations

$$[X_4, X_a] = 0 \ , \ [X_a, X_b] = i\epsilon_{abc}\alpha\phi X_c. \quad (7.35)$$

We have checked these commutation relations and found them to hold quite well for sufficiently large values of $\tilde{\alpha}$. The coordinates on the sphere are defined by

$$n_a = \frac{X_a}{\sqrt{c_2}\alpha} \ , \ \sum_a n_a^2 = \phi^2. \quad (7.36)$$

We observe that as we decrease $\tilde{\alpha}$, the radius $1/r$ jumps abruptly to 0 then starts to increase again until it becomes infinite at $\tilde{\alpha} = 0$. This is the most dramatic effect of the so-called sphere-to-matrix transition in which the sphere suddenly expands and evaporates at the transition points then it starts shrinking to zero rapidly as we lower the coupling further.

This is the interpretation advocated in [55–57] for a similar phenomena observed in the case of three dimensional bosonic models. As far as we know this phenomena was observed in Monte Carlo simulation first in [58] and it was found in analytical work on perturbative three dimensional bosonic models in [59] and then in [60].

The transitions for the bosonic mass deformed model with $\tilde{\beta} = 2/9$ and the bosonic cohomological model with $\tilde{\beta} = 0$ are observed to occur at the following estimated values

$$\tilde{\alpha}_* = 4.9 \pm 0.1 \ , \ \tilde{\beta} = 2/9. \quad (7.37)$$

$$\tilde{\alpha}_* = 2.55 \pm 0.1 \ , \ \tilde{\beta} = 0. \quad (7.38)$$

The fuzzy sphere phase corresponds to the region $\tilde{\alpha} > \tilde{\alpha}_*$ whereas the matrix phase corresponds to the region $\tilde{\alpha} < \tilde{\alpha}_*$. In other words the sphere becomes more stable as we make $\tilde{\beta}$ smaller (see below).

The order of the sphere-to-matrix transition is very difficult to determine. Since the ground state configurations are $X_4 = 0$ and $X_a = \alpha\phi L_a$, the theoretical analysis based on the effective potential of the three dimensional model done in [55, 56] should also hold here largely unchanged (see below). As a consequence we will only summarize here the main points omitting much technical details.

The specific heat $C_v = (< S^2 > - < S >^2)/(N^2 - 1)$ shown on figure (8) diverges from the side of the fuzzy sphere with a critical exponent equal 1/2. It is equal to 3 in this phase where 1/2 is due to the 2 dimensional $U(1)$ gauge field on the sphere, 1/2 is due to the normal scalar field on the sphere and 1/2 is due to the scalar field X_4. This critical behavior is typical of a second order transition. In the matrix phase the specific heat is a constant right up to the transition point and it is equal 1 where each matrix contributes 1/4. There is no divergence from this side and the critical exponent is 0. In other words the behavior above and below the critical coupling are different, which is quite unusual, but still from the specific heat we qualify this transition as second order.

The expectation values of the Yang-Mills action and the Myers (or Chern-Simons) action are shown on (10). The expectation values of the total bosonic action for the two cases $\tilde{\beta} = 2/9$ and $\tilde{\beta} = 0$ are shown on figure (11). From these observables we observe a discontinuity at the transition point. Thus the sphere-to-matrix transition is associated with a latent heat equal to $\Delta < S >=< S >_{\text{matrix}} - < S >_{\text{sphere}}$ which is typical of a first order phase transition. It is straightforward to estimate the value of this latent heat. The latent heat is released by going from the matrix phase to the fuzzy sphere phase for $\tilde{\beta} = 0$ whereas for $\tilde{\beta} = 2/9$ the latent heat is released by going in the other direction from the fuzzy sphere phase to the matrix phase.

As we will see from the discussion of the eigenvalues distributions the matrices X_μ in the matrix phase are commuting matrices centered around 0.

Phase Diagram The last point we would like to address within the context of the bosonic theory is the construction of the phase diagram in the plane $\tilde{\alpha} - \tilde{\beta}$. We have already measured two points of this phase diagram which correspond to the two values $\tilde{\beta} = 2/9$ and $\tilde{\beta} = 0$. In order to map the phase boundary between the fuzzy sphere and the matrix phase we choose other values of $\tilde{\beta}$ and measure for each one of them the critical value of $\tilde{\alpha}$ from the discontinuity in the radius $1/r$. The result is shown on figure (9).

The effective potential of the 4 dimensional bosonic Yang-Mills matrix model in the Feynman-'t Hooft background field gauge in the ground state configurations $X_4 = 0$ and $X_a = \alpha\phi L_a$ can be calculated using the method of [59]. We find

$$\frac{V_{\text{eff}}}{2c_2} = \tilde{\alpha}^4 \left[\frac{\phi^4}{4} - \frac{\phi^3}{3} + \tilde{\beta}\frac{\phi^2}{2} \right] + 2\log\phi^2. \tag{7.39}$$

The difference with the three dimensional bosonic Yang-Mills matrix model lies in the factor of 2 multiplying the logarithm. The critical line can then be obtained following the

method of [55]. We get

$$\phi_* = \frac{3}{8}(1+\sqrt{1-\frac{32\tilde{\beta}}{9}})\ ,\ \tilde{\alpha}_*^4 = \frac{16}{\phi_*^2(\phi_*^2-2\tilde{\beta})}. \tag{7.40}$$

This is the fit used on figure (9) with very reasonable agreement with the Monte Carlo data.

7.4 Dynamical Fermions: Impact of Supersymmetry

In this section we will discuss the effect of the fermion determinant. First we note that simulations with fermions are much more harder than pure bosonic simulations. The main source of complication is the evaluation of the determinant which is highly non trivial. Thermalization is very difficult and as a consequence taking the limit of large N is not so easy even with the use of the Hybrid Monte Carlo algorithm. In the bosonic case we could go as large as $N = 100$ with very decent number of statistics although in this article we have only reported data with N up to $N = 16$. In the fermionic case we will report data with N up to $N = 10$.

The first thing we have checked is the Schwinger-Dyson identity (7.24). The Monte Carlo data are shown on figure (12). The fermionic data agrees well with the prediction 6 whereas the bosonic data agrees well with the prediction 4. Note that $6 = 4 + 2$ where 4 is the number of bosonic matrices and 2 is the number of fermionic matrices.

The most important order parameter with direct significance to the underlying geometry is the radius $1/r$. See figures (13), (14) and (15). We observe that the transition sphere-to-matrix observed in the bosonic theory disappeared completely. Again it seems here that there is no major difference between the two models with $\tilde{\beta} = 2/9$ and $\tilde{\beta} = 0$. It is clear from the structure of the action that the theory with $\tilde{\alpha} = 0$ can not support the fuzzy sphere geometry and thus a phase with commuting matrices must still exist. However, the transition to the phase of commuting matrices starting from the fuzzy sphere phase seems to be a crossover transition not the second/first order behavior observer in the bosonic model. This seems to be confirmed by the behavior of the specific heat, the Yang-Mills and Myers actions and the total action shown on figures (16), (17-18) and (19) respectively. The jump and critical behavior in the specific heat and the discontinuity in the various actions disappeared.

We have to note here that the observable $< TrX_a^2 > /N$ diverges in the supersymmetric theory with $\tilde{\alpha} = \tilde{\beta} = 0$ [51]. For the mass deformed theory we have $\tilde{\beta} = 2/9$ and thus the observable $< TrX_a^2 > /N$ always exists. We observe on the second graph of figure (13) that $< TrX_a^2 > /N$ increases as we decrease $\tilde{\alpha}$ towards 0 which is consistent with the fact that it will diverge in the limit $\tilde{\alpha} \longrightarrow 0$. Qualitatively the same phenomena is observed for $\tilde{\beta} = 0$ on the second graph of figure (14) with more erratic behavior as we decrease $\tilde{\alpha}$ towards 0. However in this case we can not infer that $< TrX_a^2 > /N$ exists for all $\tilde{\alpha}$ since $\tilde{\beta} = 0$ although it looks that it does from the data. From this perspective the mass deformed model is better than the cohomologically deformed model.

We have not succeeded in determining precisely the value at which the crossover transition occurs but it seems that it depends on N in such a way that it is pushed to smaller

values of $\tilde{\alpha}$ as we increase N. From figure (15) we can see that the crossover transition for $\tilde{\beta} = 2/9$ occurs at $\tilde{\alpha} = 3.13, 2.63, 2.38$ and 2.13 for $N = 4, 6, 8$ and $N = 10$ respectively. A simple fit yields the result

$$\tilde{\alpha}_*^4 = \frac{61.13}{N^{2.38}} \ , \ \tilde{\beta} = 2/9. \tag{7.41}$$

The conjecture that the crossover transition occurs at arbitrarily small values of $\tilde{\alpha}$ in the large N limit is one of the main results of this article. In this way the fuzzy sphere is truly stable in the supersymmetric theory and does not decay. In any case we are certain that the fuzzy sphere in the supersymmetric theory is more stable compared to the bosonic theory and the crossover transition to the matrix phase is much slower. This conclusion is similar to that of [47].

7.5 Eigenvalues Distributions

Bosonic Theory A powerful set of order parameters is given by the eigenvalues distributions of the two matrices X_3 and X_4. See (20). The eigenvalues distribution of the matrix X_4 is qualitatively the same for all values of the coupling constants $\tilde{\alpha}$. However, the eigenvalues distribution of the matrix X_3 suffers a major change as we go across the transition point. In the fuzzy sphere region the eigenvalues distribution of X_3 is given by an $N-$cut distribution corresponding to the N eigenvalues $-(N-1)/2, ..., (N-1)/2$ whereas in the matrix phase the eigenvalues distribution of X_3 is identical to the eigenvalues distribution of X_4.

The eigenvalues distribution $\rho_4(x_4)$ of the matrix X_4 is always centered around 0. In the fuzzy sphere phase $\rho_4(x_4)$ depends on the coupling constant $\tilde{\alpha}$. In the matrix phase below the critical value the eigenvalues distribution $\rho_4(x_4)$ does not depend on $\tilde{\alpha}$ and coincides with the eigenvalues distribution of the non deformed model with $\tilde{\alpha} = 0$. In this region the eigenvalues distributions of the matrices X_3 and X_4 are identical.

Motivated by the work [61, 62] it was conjectured [201] that the joint eigenvalues distribution of d matrices X_1, X_2,...X_d with dynamics given by a reduced Yang-Mills action should be uniform inside a solid ball of some radius R. We have already checked that this conjecture works in three dimensions [63]. We will check now that this conjecture holds also true in four dimensions. Let $\rho(x_1, x_2, x_3, x_4)$ be the joint eigenvalues distribution of the 4 matrices X_1, X_2, X_3 and X_4. We assume that $\rho(x_1, x_2, x_3, x_4)$ is uniform inside a four dimensional ball of radius R. The normalization condition gives $\rho(x_1, x_2, x_3, x_4) = 1/V_4 = 2/\pi^2 R^4$. We want to compute the eigenvalues distribution of a single matrix, say X_4, which is induced by integrating out the other three matrices. We compute

$$\Big[\int_{-R}^{R} dx_4 \int_{-R}^{R} dx_3 \int_{-R}^{R} dx_2 \int_{-R}^{R} dx_1\Big]_{x_1^2+x_2^2+x_3^2+x_4^2\leq R^2} =$$
$$\int_{-R}^{R} dx_4 \Big[\int_{-R}^{R} dx_3 \int_{-R}^{R} dx_2 \int_{-R}^{R} dx_1\Big]_{x_1^2+x_2^2+x_3^2\leq R^2-x_4^2} =$$
$$\int_{-R}^{R} dx_4 \Big[\int r^2 dr d\Omega_3\Big]_{r^2\leq R^2-x_4^2} =$$
$$\frac{4\pi}{3}\int_{-R}^{R} dx_4 (R^2-x_4^2)^{\frac{3}{2}}. \tag{7.42}$$

We obtain therefore the eigenvalues distribution

$$\rho_4(x_4) = \frac{8}{3\pi R^4}(R^2-x_4^2)^{\frac{3}{2}}. \tag{7.43}$$

This is precisely the fit shown on figure (20) with a measured value of R for $\tilde{\beta}=0$ and $\tilde{\alpha}=0$ given by

$$R_0 = 1.826 \pm 0.004. \tag{7.44}$$

The above eigenvalues distribution works better for the theory with $\tilde{\beta}=2/9$ as shown on figure (22) with a similar measured value of R given for $\tilde{\alpha}=0.25$ by

$$R_{2/9} = 1.815 \pm 0.008. \tag{7.45}$$

We have found that these two measured values are almost the same throughout the matrix phase.

We emphasize that $\rho_4(x_4)$ is the eigenvalues distribution of the matrix X_4 not only in the matrix phase but also in the fuzzy sphere phase with a value of R which depends on the coupling constant $\tilde{\alpha}$. We also emphasize that $\rho_4(x_3)$ is the eigenvalues distribution of the matrix X_3 in the matrix phase for the bosonic theory for both values $\tilde{\beta}=0$ and $\tilde{\beta}=2/9$.

Another non trivial check for this important conjecture is the theoretical prediction of the radius

$$\begin{aligned} <\frac{1}{N}TrX_a^2> &= 3<\frac{1}{N}TrX_3^2> \\ &= 3\int_{-R}^{R} dx_4 \rho_4(x_4) x_4^2 \\ &= \frac{R^2}{2}. \end{aligned} \tag{7.46}$$

This means that in the matrix phase the order parameter $<\frac{1}{N}TrX_a^2>$, which is related to the radius, is constant. Indeed, this is what we see on figure (7) with a good agreement between the Monte Carlo measurement and the theoretical prediction. The observed value of $<\frac{1}{N}TrX_a^2>$ is slightly below the theoretical prediction for $\tilde{\beta}=2/9$ throughout. This

is not the case for $\tilde{\beta} = 0$ where the Monte Carlo measurement starts slightly below $R^2/2$ and then rises above it as we approach the transition to the fuzzy sphere.

This can potentially be a serious difference between the tow cases $\tilde{\beta} = 2/9$ and $\tilde{\beta} = 0$. The transition to the sphere in the case of $\tilde{\beta} = 2/9$ is in the form of an abrupt jump but in the case of $\tilde{\beta} = 0$ there is a slow rise in the matrix phase as we increase $\tilde{\alpha}$ before the actual jump.

The main conclusion of these successful measurements is the fact that the matrices X_μ in the matrix phase are commuting and thus they are diagonalizable with a joint eigenvalues distribution which is uniform inside a ball of dimension R.

Supersymmetric Theory In the supersymmetric case we found it much easier to compute eigenvalues distributions with the value $\tilde{\beta} = 2/9$ and thus we will only consider here the mass deformed model. A sample of the eigenvalues distributions of the mass deformed model is shown on figures (21) and (22).

Again it is observed that the eigenvalues distribution of X_3 in the fuzzy sphere phase is given by an $N-$cut distribution corresponding to the N eigenvalues $-(N-1)/2, ..., (N-1)/2$ whereas in the matrix phase the eigenvalues distributions of X_3 is given by $\rho_4(x_3)$ with a much larger value of R given for $\tilde{\alpha} = 0.25$ by

$$R = 2.851 \pm 0.009. \tag{7.47}$$

The eigenvalues distribution of X_4 is always centered around 0 given by $\rho_4(x_4)$ with a value of R which depends on the coupling constant $\tilde{\alpha}$. This eigenvalues distribution coincides with the eigenvalues distribution of X_3 deep inside the matrix phase below $\tilde{\alpha} = 0.25$.

The eigenvalues distribution ρ_4 is therefore universal in the sense that it describes the behavior of the eigenvalues of the matrix X_4 for all values of $\tilde{\alpha}$ and all values of $\tilde{\beta}$ and the behavior of the eigenvalues of the matrix X_3 in the matrix phase for all values of $\tilde{\beta}$. We note here the difference between this eigenvalues distribution ρ_4 and the eigenvalues distribution of the supersymmetric model with $\tilde{\alpha} = \tilde{\beta} = 0$ [51]. In the latter case the distribution extends from $-\infty$ to $+\infty$ and goes as $1/x^3$ for large eigenvalues. It is not clear to us at this stage how the two distributions relate to each other.

The point at which the eigenvalues distributions of X_3 and X_4 coincide may be taken as the measure for the crossover transition point and thus for $N = 10$ this occurs at a point between $\tilde{\alpha} = 1$ and $\tilde{\alpha} = 0.25$.

7.6 Remarks: $D = 3$ Yang-Mills Matrix Models and Scalar Fluctuations

The $D = 3$ Yang-Mills matrix models we can immediately consider here can be obtained from the above $D = 4$ models by simply setting the fourth matrix X_4 to zero. This is different from the IKKT supersymmetric Yang-Mills matrix model in $D = 3$ by the fact that it involves a determinant instead of a Pffafian and as a consequence the path integrals of these theories are convergent.

The physics of these $D = 3$ models is identical to the physics of the $D = 4$ models in the sense that there is a first/second order phase transition from a background geometry (the fuzzy sphere) to commuting matrices which in the presence of dynamical fermions is turned into a slow crossover transition. The most important difference is the natural expectation that the eigenvalues distributions of the matrices X_a in the matrix phase must be distributed according to the formula

$$\rho_3(x_3) = \frac{3}{4R^3}(R^2 - x_3^2). \tag{7.48}$$

By analogy with the $D = 4$ formula (7.43) this distribution can be derived from the assumption that the joint eigenvalues distribution of the 3 matrices X_1, X_2, X_3 is uniform inside a three dimensional ball of radius R. In the next section we will also derive this distribution for the $D = 4$ Yang-Mills matrix model with a particular choice of the parameters with $\beta_4 \neq 0$ (see (7.1)).

Monte Carlo measurment of the radius gives the value

$$R \simeq 2. \tag{7.49}$$

As shown on the first graph of the figure (23) a sample of the data for the $N = 10$ three-dimensional bosonic Yang-Mills matrix model with $\tilde{\beta} = 2/9$ and $\tilde{\alpha} = 0.5$ is shown. Clearly it can be fit nicely to (7.48) with $R = 2$. In performing the fitting in three dimensions we have to cut the tails in order to get a sensible answer. As it turns out the same three dimensional data can also be fit to the four dimensional prediction (7.43). We also show the data for the $N = 10$ four-dimensional bosonic Yang-Mills matrix model with $\tilde{\beta} = 2/9$ and $\tilde{\alpha} = 0.5$ for comparison.

In the Monte Carlo data of the $D = 3$ Yang-Mills matrix models reported in this article it was not possible to resolve the ambiguity between the two fits (7.43) and (7.48). However high precision runs performed in [202] seems to indicate that indeed the three dimensional prediction (7.48) is the correct behavior for the eigenvalues distributions of the $D = 3$ Yang-Mills matrix models.

The second remark we would like to discuss in this section concerns the dependence on N and $\tilde{\alpha}$ of the eigenvalues distributions ρ_4 and ρ_3 given in (7.43) and (7.48) respectively. As shown on the second graph of the figure (23) the distributions ρ_4 and ρ_3 are independent of $\tilde{\alpha}$. Similarly we can show that these distributions are independent of N.

The third remark concerns the eigenvalues distributions of the normal scalar field in the fuzzy sphere phase which is define by $\phi = (X_a^2 - \phi^2 c_2)/(2\phi\sqrt{c_2})$ [59]. This is shown on figure (24) for both the $D = 3$ and $D = 4$ models. The behavior in both cases is the same although we have to note that the effective values $c_{2,\text{eff}}$ in $D = 3$ and $D = 4$ are slightly different. This is quite natural as the three dimensional model is more stable in the sense that it has a lower critical value $\tilde{\alpha}_*$. The central observation here is that we can nicely fit these eigenvalues distributions to the eigenvalues distribution ρ_4 given in (7.43) as shown on figure (24).

8 Elements of the Solution of the $D = 3$ Theory

8.1 Localization: Reduction to $D = 3$ Chern-Simons Theory

We start by summarizing our main results of section 3. The action of the theory of interest consists of two terms $S_{\rm cohom}$ and $\hat{S}$, viz $S_{\rm def} = S_{\rm cohom} + \hat{S}$ [3]. The first piece $S_{\rm cohom}$ is the standard $\mathcal{N} = 1$ Yang-Mills matrix theory in $D = 4$ which has 4 supercharges whereas the second piece $\hat{S}$ is the cohomological deformation which preserves two of the supercharges. The parameters of the deformation were fixed so that the action (after the integration of the BRST field H) corresponds to a generalization of the mass deformed action considered in section 2 with mass terms for the bosonic and fermionic matrices and a Myers term. Effectively the action $S_{\rm def}$ will be the sum of two actions $S_{\rm cohom}$ and $\Delta S_{\rm cohom}$ given by

$$S_{\rm cohom} = -\frac{1}{8}Tr[X_\mu, X_\nu]^2 - \frac{1}{2}Tr\theta^+\Big(i[X_4, ..] + \sigma_a[X_a, ..]\Big)\theta + TrB^2. \tag{8.1}$$

$$\Delta S_{\rm cohom} = \frac{\kappa_1}{2}Tr\theta^+\theta + \frac{1}{2}\epsilon\kappa_1 TrX_a^2 + \frac{1}{4}\kappa_1(2\epsilon - \kappa_1)TrX_4^2 - \frac{i}{6}(4\epsilon + \kappa_1)\epsilon_{abc}TrX_aX_bX_c. \tag{8.2}$$

The first supercharge of this cohomologically deformed theory corresponds to the supersymmetry transformations

$$d_{\rm def}X_i = \chi_i. \tag{8.3}$$

$$d_{\rm def}\phi = 0 \ , \ d_{\rm def}\bar{\phi} = -\eta_2. \tag{8.4}$$

$$d_{\rm def}H = [\phi, \eta_1] + i(\kappa_2 + \kappa_1)\eta_2. \tag{8.5}$$

$$d_{\rm def}\eta_1 = H + (-i(4\epsilon - \kappa_1)\phi + i(\kappa_2 + \kappa_1)\bar{\phi}) \ , \ d_{\rm def}\eta_2 = [\bar{\phi}, \phi]. \tag{8.6}$$

$$d_{\rm def}\chi_i = [\phi, X_i] + i\epsilon\epsilon_{ij}X_j. \tag{8.7}$$

The second supercharge can be obtained by an appropriate permutation of the spinors η_i and χ_i [48].

We observe that we have three parameters κ_1, κ_2 and ϵ where κ_2 does not appear in the action. Thus the path integral does not depend on κ_2. We note that in [48] a different cohomological deformation was considered for which it was pssible to show explicitly that the path integral is independent of κ_2. In summary we have then two deformation parameters κ_1 and ϵ or equivalently α and ζ_0 defined in equation (6.73). For our purposes

[3] In fact the action that should be considered is $2S_{\rm def}/g^2$.

α will play the role of the gauge coupling constant while ζ_0 is the actual parameter of the cohomological/mass deformation.

The theory with $\kappa_2 = 0$ will yield the same action (8.1)+(8.2) with the supersymmetry transformations

$$d_{\rm def} X_i = \chi_i. \tag{8.8}$$

$$d_{\rm def}\phi = 0 \ , \ d_{\rm def}\bar{\phi} = -\eta_2. \tag{8.9}$$

$$d_{\rm def} H \ = \ [\phi, \eta_1] + i\kappa_1\eta_2. \tag{8.10}$$

$$d_{\rm def}\eta_1 = H + (-i(4\epsilon - \kappa_1)\phi + i\kappa_1\bar{\phi}) \ , \ d_{\rm def}\eta_2 = [\bar{\phi}, \phi]. \tag{8.11}$$

$$d_{\rm def}\chi_i \ = \ [\phi, X_i] + i\epsilon\epsilon_{ij}X_j. \tag{8.12}$$

We note that the action for the value $\kappa_1 = 2\epsilon$ corresponds precisely to the mass deformed action considered in section 2 and as a consequence the above supersymmetry transformations (8.8)-(8.12) will correspond to one of the mass deformed supercharges.

The path integral we wish to evaluate is

$$Z \ = \ \int dX_\mu \ dB \ d\theta^+ \ d\theta \ \exp(-S_{\rm cohom} - \Delta S_{\rm cohom}). \tag{8.13}$$

This can be obtained from the path integral (with $S_{\rm def}[\kappa_2 = 0] = S_{\rm cohom} + \hat{S}[\kappa_2 = 0]$)

$$Z \ = \ \int dX_1 \ dX_2 \ d\bar{\phi} \ d\phi \ dH \ d\chi_1 \ d\chi_2 \ d\eta_1 \ d\eta_2 \ \exp(-S_{\rm def}[\kappa_2 = 0]). \tag{8.14}$$

In this equation the actions $S_{\rm cohom}$ and $\hat{S}$ must be expressed in terms of the BRST fields H, ϕ, $\bar{\phi}$, X_i, η_i and χ_i, viz

$$\begin{aligned} S_{\rm cohom} \ &= \ Tr\big(H^2 + H[X_1, X_2] + [X_i, \phi][X_i, \bar{\phi}] + [\phi, \bar{\phi}]^2 - \eta_i[\phi, \eta_i] - \chi_i[\bar{\phi}, \chi_i] \\ &- \ \eta_1\epsilon^{ij}[\chi_i, X_j] + \eta_2[\chi_i, X_i]\big). \end{aligned} \tag{8.15}$$

$$\begin{aligned} \hat{S}[\kappa_2 = 0] \ &= \ i\kappa_1 Tr(\chi_1\chi_2 - \eta_1\eta_2) - 4i\epsilon Tr\phi[X_1, X_2] + i(\kappa_1 + 2\epsilon)Tr\bar{\phi}[X_1, X_2] \\ &+ \ i\kappa_1 Tr\bar{\phi}H - i(4\epsilon - \kappa_1)Tr\phi H - 2\epsilon(2\epsilon - \kappa_1)Tr\phi^2 + \frac{1}{2}\epsilon\kappa_1 Tr X_i^2. \end{aligned} \tag{8.16}$$

To perform the above path integral (8.14) we will now add the terms proportional to κ_2 and since the resulting action remains independent of κ_2 we will take the limit $\kappa_2 \longrightarrow \infty$ in which the path integral localizes. We have

$$\begin{aligned} Z \ &= \ \int dX_\mu \ dB \ d\theta^+ \ d\theta \ \exp(-S_{\rm cohom} - \Delta S_{\rm cohom}) \\ &= \ \int dX_1 \ dX_2 \ d\bar{\phi} \ d\phi \ dH \ d\chi_1 \ d\chi_2 \ d\eta_1 \ d\eta_2 \ \exp(-S_{\rm def}[\kappa_2 = 0] - \kappa_2\Delta\hat{S}). \end{aligned} \tag{8.17}$$

$$\Delta\hat{S} \;=\; iTr\eta_1\eta_2 + iTr\bar{\phi}H + (4\epsilon-\kappa_1)Tr\bar{\phi}\phi - \kappa_1 Tr\bar{\phi}^2. \tag{8.18}$$

In the limit $\kappa_2 \longrightarrow \infty$ we are able to integrate the BRST quartet η_1, η_2, H and $\bar{\phi}$. The fermionic part of the action which depends on κ_2 is

$$i\kappa_2 Tr\eta_1\eta_2. \tag{8.19}$$

Thus by using the saddle point method we obtain

$$\int d\eta_1\; d\eta_2\; f(\eta_1,\eta_2)\; e^{-i\kappa_2 Tr\eta_1\eta_2} = \kappa_2^{N^2-1} i^{N^2-1} N f(0,0). \tag{8.20}$$

The actions $S_{\rm cohom}$ and $\hat{S}[\kappa_2=0]$ reduce to

$$S_{\rm cohom} \;=\; Tr\Big(H^2 + H[X_1,X_2] + [X_i,\phi][X_i,\bar{\phi}] + [\phi,\bar{\phi}]^2 - \chi_i[\bar{\phi},\chi_i]\Big). \tag{8.21}$$

$$\begin{aligned}\hat{S}[\kappa_2=0] \;&=\; i\kappa_1 Tr\chi_1\chi_2 - 4i\epsilon Tr\phi[X_1,X_2] + i(\kappa_1+2\epsilon)Tr\bar{\phi}[X_1,X_2] \\ &+\; i\kappa_1 Tr\bar{\phi}H - i(4\epsilon-\kappa_1)Tr\phi H - 2\epsilon(2\epsilon-\kappa_1)Tr\phi^2 + \frac{1}{2}\epsilon\kappa_1 TrX_i^2.\end{aligned} \tag{8.22}$$

Next we do the path integral over H then X_3 in that order using again the saddle point method. The relevant terms are the bosonic contributions which are proportional to κ_2. They are given by

$$(4\epsilon-\kappa_1)\kappa_2 Tr\bar{\phi}\phi - \kappa_1\kappa_2 Tr\bar{\phi}^2 + i\kappa_2 Tr\bar{\phi}H. \tag{8.23}$$

For $\epsilon<0$ we can verify that the integral over X_3 is exponentially damped and therefore we can shift X_3 appropriately. The resulting integral over H turns out also to be damped exponentially. Explicitly we have

$$\begin{aligned}(4\epsilon-\kappa_1)\kappa_2 Tr\bar{\phi}\phi - \kappa_1\kappa_2 Tr\bar{\phi}^2 + i\kappa_2 Tr\bar{\phi}H \;&=\; -\epsilon\kappa_2 Tr\big(X_3 + \frac{i}{4\epsilon}(H-\kappa_1 X_4)\big)^2 \\ &-\; \frac{\kappa_2}{16\epsilon}Tr(H+(4\epsilon-\kappa_1)X_4)^2 + \frac{\kappa_2}{2}(4\epsilon-\kappa_1)TrX_4^2.\end{aligned} \tag{8.24}$$

In the limit $\kappa_2 \longrightarrow \infty$ the hermitian matrix H will be localized around $-(4\epsilon-\kappa_1)X_4 = i(4\epsilon-\kappa_1)(\phi+\bar{\phi})$. The above equation reduces to

$$(4\epsilon-\kappa_1)\kappa_2 Tr\bar{\phi}\phi - \kappa_1\kappa_2 Tr\bar{\phi}^2 + i\kappa_2 Tr\bar{\phi}H \;=\; -\epsilon\kappa_2 Tr(X_3-iX_4)^2 + \frac{\kappa_2}{2}(4\epsilon-\kappa_1)TrX_4^2. \tag{8.25}$$

Equivalently

$$(4\epsilon-\kappa_1)\kappa_2 Tr\bar{\phi}\phi - \kappa_1\kappa_2 Tr\bar{\phi}^2 + i\kappa_2 Tr\bar{\phi}H \;=\; -4\epsilon\kappa_2 Tr\bar{\phi}^2 - \frac{\kappa_2}{2}(4\epsilon-\kappa_1)Tr(\phi+\bar{\phi})^2. \tag{8.26}$$

We can now shift the integral over X_3 as $X_3 \longrightarrow \bar{\phi} = -\frac{1}{2}(X_3 - iX_4)$. Clearly we can now assume that $\bar{\phi}$ is hermitian. For consistency we will also shift the integral over X_4 as

$X_4 \longrightarrow \phi = iX_4 - \bar{\phi}$. In the limit $\kappa_2 \longrightarrow \infty$ the hermitian matrix $\bar{\phi}$ is localized around 0. The matrix ϕ is then seen to be antihermitian identified with iX_4.

We get thus by using the saddle point method the result

$$\int d\bar{\phi}\ dH\ f(\bar{\phi}, H)\ e^{(4\epsilon-\kappa_1)\kappa_2 Tr\bar{\phi}\phi - \kappa_1\kappa_2 Tr\bar{\phi}^2 + i\kappa_2 Tr\bar{\phi}H} \quad = \quad \kappa_2^{1-N^2}(2\pi)^{N^2-1}\frac{1}{N}f(0, i(4\epsilon-\kappa_1)\phi)e^{\frac{\kappa_2}{2}(4\epsilon-\kappa_1)Tr\phi^2}. \tag{8.27}$$

The κ_2 dependence cancels completely if we choose $4\epsilon = \kappa_1$. The actions $S_{\rm cohom}$ and $\hat{S}[\kappa_2 = 0]$ reduce to

$$S_{\rm cohom} \quad = \quad Tr\Big(- (4\epsilon-\kappa_1)^2\phi^2 + i(4\epsilon-\kappa_1)\phi[X_1, X_2]\Big). \tag{8.28}$$

$$\begin{aligned}\hat{S}[\kappa_2 = 0] \quad &= \quad i\kappa_1 Tr\chi_1\chi_2 - 4i\epsilon Tr\phi[X_1, X_2] + (4\epsilon-\kappa_1)^2 Tr\phi^2 + 2\epsilon(\kappa_1 - 2\epsilon)Tr\phi^2 \\ &+ \quad \frac{1}{2}\epsilon\kappa_1 Tr X_i^2.\end{aligned} \tag{8.29}$$

The integration over the last fermionic degrees of freedom χ_1 and χ_2 is now trivial since they are free degrees of freedom decoupled from everything else. We end up with the model

$$\begin{aligned}Z \quad &= \quad \int d\phi\ dX_1\ dX_2 \exp\Big(i\kappa_1 Tr\phi[X_1, X_2] - 2\epsilon(\kappa_1 - 2\epsilon)Tr\phi^2 - \frac{1}{2}\epsilon\kappa_1 Tr X_i^2 \\ &+ \quad \frac{\kappa_2}{2}(4\epsilon-\kappa_1)Tr\phi^2\Big).\end{aligned} \tag{8.30}$$

This is essentially the path integral of two-dimensional gauge theory on the fuzzy sphere studied in [70]. As was shown in [71] it can also be derived from the reduction to zero dimension of Chern-Simons theory on $\mathbf{S}^3$.

We can therefore conclude that the mass deformation considered here reduces the 4-dimensional supersymmetric theory to a bosonic $D = 3$ matrix theory which when expanded about the ground state yields a noncommutative gauge theory on the fuzzy sphere.

8.2 Exact Integration: Emergence of the Fuzzy Sphere

In the previous section we have found that $\bar{\phi} = -(X_3 - iX_4)/2$ is localized around 0 which means that the most important configurations satisfy $X_3 - iX_4 = 0$. Since $\phi = iX_4 - \bar{\phi}$ we can think of ϕ as iX_4, i.e. ϕ is antihermitian, and as a consequence the cubic term is not real and the mass term of ϕ is of the wrong sign.

Formally we can also think of ϕ as a hermitian matrix which can be identified with X_3. The cubic term in this case is real which is precisely a Chern-Simon term and the mass term of ϕ is of the correct sign. This can be seen by rewriting in the limit $\kappa_2 \longrightarrow \infty$ the path integration over X_3 and X_4 as (see equation (8.25))

$$\int dX_3 \int dX_4 \exp\Big(\epsilon\kappa_2 Tr(X_3 - iX_4)^2 - \frac{\kappa_2}{2}(4\epsilon-\kappa_1)Tr X_4^2\Big)(...) \quad \sim \quad \int dX_3 \int dX_4 \delta(X_3 - iX_4)\exp\Big(- \frac{\kappa_2}{2}(4\epsilon-\kappa_1)Tr X_4^2\Big)(...). \tag{8.31}$$

Instead of doing the integral over X_3 first then over X_4 by performing the shift $X_3 \longrightarrow \bar{\phi} = -(X_3 - iX_4)/2$, $X_4 \longrightarrow \phi = iX_4 - \bar{\phi}$ we will do the integral over X_4 first then over X_3 by performing the shift $X_4 \longrightarrow \bar{\phi} = -(X_3 - iX_4)/2$, $X_3 \longrightarrow \phi = X_3 + \bar{\phi}$.

In the following we will therefore assume that ϕ is a hermitian matrix identified with X_3. Furthermore recall that $\epsilon < 0$ and as a consequence we will take $\kappa_1 < 0$ and $\kappa_1 - 2\epsilon < 0$ in order to have mass terms for ϕ and X_i. Since $\epsilon = -\alpha(1 + 6\zeta_0)/6$ and $\kappa_1 - 2\epsilon = 6\zeta_0\alpha$ we conclude that we must have $-1/6 \leq \zeta_0 < 0$. We have already found that we must have $0 \leq \zeta_0 \leq 1/12$ in order to have a stable classical theory in the direction X_4 and that the value $\zeta_0 = 0$ corresponds precisely to the mass deformed theory of interest which is constructed in section 2.

In the current case we have to take the value $4\epsilon = \kappa_1$, or equivalently $\zeta_0 = -1/24$, which is the value at which the dependence on κ_2 drops completely. For this value the field X_4 will have a negative mass but the original theory remains stable in the X_4 as one might easily check in the fuzzy sphere region.

We introduce

$$t = 2\epsilon^3(\kappa_1 - 2\epsilon) = -\frac{\alpha^4}{18}\zeta_0(1 + 6\zeta_0)^3. \tag{8.32}$$

Furthermore since $\bar{\phi}$ is localized around 0 we can identify ϕ with X_3. In order to make $SO(3)$ covariance manifest we perform the rescaling

$$X_i \longrightarrow -2\epsilon\sqrt{\frac{\kappa_1 - 2\epsilon}{\kappa_1}}X_i \ , \ \phi \longrightarrow -\epsilon\phi. \tag{8.33}$$

The path integral becomes (with $4\epsilon = \kappa_1$)

$$Z = \int d\phi \ dX_1 \ dX_2 \exp t\Big(- 2iTr\phi[X_1, X_2] - Tr\phi^2 - TrX_i^2\Big). \tag{8.34}$$

We perform now the scaling (6.78). We get then

$$Z = \int d\phi \ dX_1 \ dX_2 \exp Nt\Big(- 2iTr\phi[X_1, X_2] - Tr\phi^2 - TrX_i^2\Big). \tag{8.35}$$

$$t \ = \ -\frac{16\alpha^4}{9}\zeta_0(1 + 6\zeta_0)^3. \tag{8.36}$$

For $4\epsilon = \kappa_1$ we have explicitly

$$t \ = \ \frac{\alpha^4}{32}. \tag{8.37}$$

The classical equations of motion are

$$[X_1, X_2] = i\phi \ , \ [X_2, \phi] = iX_1 \ , \ [\phi, X_1] = iX_2. \tag{8.38}$$

The solutions are given by $SU(2)$ irreducible representations, namely

$$X_i = L_i \ , \ \phi = L_3. \tag{8.39}$$

We perform now the integrals over X_1 and X_2. By integrating over X_2 we get

$$Z = \int d\phi\ dX_1 \exp Nt\Big(- Tr[\phi, X_1]^2 - Tr\phi^2 - TrX_1^2\Big). \tag{8.40}$$

Next we diagonalize the hermitian matrix ϕ. We have

$$d\phi = \prod_{i=1}^{N} d\phi_i \prod_{i<j}(\phi_i - \phi_j)^2. \tag{8.41}$$

We get then

$$Z = \int \prod_{i=1}^{N} d\phi_i \prod_{i<j}(\phi_i - \phi_j)^2 \int dX_1 \exp\Big(- \sum_{i,j}(X_1)_{ij}(X_1)^*_{ij}\Big[- Nt(\phi_i - \phi_j)^2 + Nt\Big] - Nt\sum_i \phi_i^2\Big). \tag{8.42}$$

Integrating over X_1 we get

$$Z = \int \prod_{i=1}^{N} d\phi_i \prod_{i<j}(\phi_i - \phi_j)^2 \det\Big(- Nt(\phi_i - \phi_j)^2 + Nt\Big)^{-1} \exp\Big(- Nt\sum_i \phi_i^2\Big). \tag{8.43}$$

Let us compute the determinant for $N = 3$. Clearly $t \longrightarrow 0$ when $\alpha \longrightarrow 0$. Thus we have in the limit $\alpha \longrightarrow 0$ (with $t_{ij} = -Nt(\phi_i - \phi_j)^2 + Nt$)

$$\det\Big(- Nt(\phi_i - \phi_j)^2 + Nt\Big) = 2t_{12}t_{13}t_{23} + t_{11}^3 - t_{11}(t_{12}^2 + t_{13}^2 + t_{23}^2). \tag{8.44}$$

But t_{11} is proportional to α. In other words t_{11} vanishes if $\alpha \longrightarrow 0$. In this case the detreminant is given by

$$\det\Big(- Nt(\phi_i - \phi_j)^2 + Nt\Big)^{-1} \propto \prod_{i<j}\Big(- Nt(\phi_i - \phi_j)^2 + Nt\Big)^{-1}. \tag{8.45}$$

The generalization of this result to higher N is straightforward. This result is actually exact and it does not require taking the limit $\alpha \longrightarrow 0$ [67]. The path integral becomes

$$Z = \int \prod_{i=1}^{N} d\phi_i \prod_{i<j}(\phi_i - \phi_j)^2 \prod_{i<j}\Big(- Nt(\phi_i - \phi_j)^2 + Nt\Big)^{-1} \exp\Big(- Nt\sum_i \phi_i^2\Big). \tag{8.46}$$

This can also put in the form (with $t = 1/g^2$)

$$Z = \int \prod_{i=1}^{N} d\phi_i \prod_{i\neq j} \frac{\phi_i - \phi_j}{\phi_i - \phi_j + 1} \exp\Big(- \frac{N}{g^2}\sum_i \phi_i^2\Big). \tag{8.47}$$

We will use the Cauchy formula

$$\sum_{\sigma\in\mathcal{S}_N}(-1)^\sigma\prod_{i=1}^N\left(\frac{f(\phi_i)}{\phi_i-\phi_{\sigma(i)}+1}\right) \;=\; \prod_{i=1}^N f(\phi_i)\prod_{i\neq j}\frac{\phi_i-\phi_j}{\phi_i-\phi_j+1}. \tag{8.48}$$

It is quite illuminating to illustrate this identity for smaller values of N. For example we consider $N=3$. We have

$$\begin{aligned}\sum_{\sigma\in\mathcal{S}_3}(-1)^\sigma\prod_{i=1}^3\left(\frac{f(\phi_i)}{\phi_i-\phi_{\sigma(i)}+1}\right) &= \Big[\frac{1}{\phi_1-\phi_1+1}\frac{1}{\phi_2-\phi_2+1}\frac{1}{\phi_3-\phi_3+1}\\ &+ \frac{1}{\phi_1-\phi_3+1}\frac{1}{\phi_2-\phi_1+1}\frac{1}{\phi_3-\phi_2+1}\\ &+ \frac{1}{\phi_1-\phi_2+1}\frac{1}{\phi_2-\phi_3+1}\frac{1}{\phi_3-\phi_1+1}\\ &- \frac{1}{\phi_1-\phi_1+1}\frac{1}{\phi_2-\phi_3+1}\frac{1}{\phi_3-\phi_2+1}\\ &- \frac{1}{\phi_1-\phi_3+1}\frac{1}{\phi_2-\phi_2+1}\frac{1}{\phi_3-\phi_1+1}\\ &- \frac{1}{\phi_1-\phi_2+1}\frac{1}{\phi_2-\phi_1+1}\frac{1}{\phi_3-\phi_3+1}\Big]f(\phi_1)f(\phi_2)f(\phi_3).\end{aligned} \tag{8.49}$$

We introduce the notation $T_{ij}=\phi_i-\phi_j$. Then we have

$$\begin{aligned}\sum_{\sigma\in\mathcal{S}_3}(-1)^\sigma\prod_{i=1}^3\left(\frac{f(\phi_i)}{\phi_i-\phi_{\sigma(i)}+1}\right) &= \frac{f(\phi_1)f(\phi_2)f(\phi_3)}{(T_{12}+1)(T_{21}+1)(T_{13}+1)(T_{31}+1)(T_{23}+1)(T_{32}+1)}\Big[\\ &- (T_{12}^2-1)(T_{13}^2-1)(T_{23}^2-1)+(-T_{13}+1)(T_{12}+1)(T_{23}+1)\\ &+ (-T_{12}+1)(-T_{23}+1)(T_{13}+1)-(T_{12}^2-1)(T_{13}^2-1)\\ &- (T_{12}^2-1)(T_{23}^2-1)-(T_{13}^2-1)(T_{23}^2-1)\Big]\\ &= \frac{f(\phi_1)f(\phi_2)f(\phi_3)}{(T_{12}+1)(T_{21}+1)(T_{13}+1)(T_{31}+1)(T_{23}+1)(T_{32}+1)}\Big[-T_{12}^2T_{13}^2T_{23}^2\\ &+ (T_{12}-T_{13}+T_{23})^2\Big]\\ &= f(\phi_1)f(\phi_2)f(\phi_3)\prod_{i\neq j}\frac{T_{ij}}{T_{ij}+1}.\end{aligned} \tag{8.50}$$

By using the Cauchy formula the partition function becomes

$$Z \;=\; \sum_{\sigma\in\mathcal{S}_N}(-1)^\sigma\int\prod_{i=1}^N\left(d\phi_i\frac{e^{-\frac{N}{g^2}\phi_i^2}}{\phi_i-\phi_{\sigma(i)}+1}\right). \tag{8.51}$$

From our earlier considerations it is natural to understand the integrals as contour integrals. The poles are on the real line so we regularize this partition function as follows

$$Z_\beta \;=\; \sum_{\sigma\in\mathcal{S}_N}(-1)^\sigma\oint\prod_{i=1}^N\left(d\phi_i\frac{e^{-\frac{N}{g^2}\phi_i^2+i\beta\phi_i}}{\phi_i-\phi_{\sigma(i)}+1+i\beta}\right),\ \beta>0. \tag{8.52}$$

Thus we close the contours in the upper half-plane. The reason behind this way of regularization is twofold. Firstly among the two poles which may appear for each variable only one will be counted. Secondly the result obtained here will be consistent with the result for Yang-Mills quantum mechanics obtained in [68].

Since the eigenvalues ϕ_i are defined up to a permutation we must also incorporate a combinatorial factor equal $1/N!$. Furthermore the tracelessness condition $Tr\phi = 0$ must be included in the form $N\delta(\phi_1 + ... + \phi_N)$. In summary we get the partition function

$$Z_\beta = \frac{1}{(N-1)!}\sum_{\sigma\in\mathcal{S}_N}(-1)^\sigma \oint \delta(\phi_1+...+\phi_N)\prod_{i=1}^{N}\left(d\phi_i \frac{e^{-\frac{N}{g^2}\phi_i^2+i\beta\phi_i}}{\phi_i-\phi_{\sigma(i)}+1+i\beta}\right). \quad (8.53)$$

Among the $N!$ integrals there are $(N-1)!$ which are non zero. Let us check this in the case of $N = 3$. The contour integrals over ϕ_1, ϕ_2 and ϕ_3 of the last three terms respectively in (8.49) vanish because there are no poles in these variables. The first term in (8.49) vanishes because the contour integrals over ϕ_1, ϕ_2 and ϕ_3 vanish separately. The second and third term in (8.49) lead to identical contributions given by

$$Z_\beta = (-1)^2\frac{2!}{2!}\oint \delta(\phi_1+\phi_2+\phi_3)\prod_{i=1}^{3}\left(d\phi_i \frac{e^{-\frac{3}{g^2}\phi_i^2+i\beta\phi_i}}{\phi_i-\phi_{i-1}+1+i\beta}\right),\ \phi_0=\phi_3. \quad (8.54)$$

In general we get

$$Z_\beta = (-1)^{N-1}\frac{(N-1)!}{(N-1)!}\oint \delta(\phi_1+...+\phi_N)\prod_{i=1}^{N}\left(d\phi_i \frac{e^{-\frac{N}{g^2}\phi_i^2+i\beta\phi_i}}{\phi_i-\phi_{i-1}+1+i\beta}\right),\ \phi_0=\phi_N. \quad (8.55)$$

Next we will perform the integrals over the variables ϕ_2,...,ϕ_{N-1} using the residue theorem. The two remaining integrals over ϕ_1 and ϕ_N will be constrained such that $\phi_1 + \phi_N = 0$. To see this explicitly we try one more time a small value of N say $N = 4$. We have with the notation $i\gamma = 1 + i\beta$ the partition function

$$Z_\beta = (-1)^{4-1}\oint \delta(\phi_1+\phi_2+\phi_3+\phi_4)\prod_{i=1}^{4}\left(d\phi_i \frac{e^{-\frac{4}{g^2}\phi_i^2+i\beta\phi_i}}{\phi_i-\phi_{i-1}+i\gamma}\right). \quad (8.56)$$

The pole in the ϕ_2-plane is at $\phi_2 = \phi_3+i\gamma$ and the pole in the ϕ_3-plane is at $\phi_3 = \phi_4+i\gamma$. By using the residue theorem we get

$$\begin{aligned} Z_\beta &= (-1)^{4-1}\Big[-(-2\pi i)^2\oint d\phi_1 d\phi_4 \delta(\phi_1+3\phi_4+3i\gamma)\ e^{-\frac{4}{g^2}\left(\phi_1^2+(\phi_4+2i\gamma)^2+(\phi_4+i\gamma)^2+\phi_4^2\right)} \\ &\times\ e^{i\beta\left(\phi_1+(\phi_4+2i\gamma)+(\phi_4+i\gamma)+\phi_4\right)}\frac{1}{\phi_1-\phi_4+i\gamma}\frac{1}{\phi_1-\phi_4-3i\gamma}\Big]. \end{aligned} \quad (8.57)$$

In general there will be a pole in the ϕ_2-plane at $\phi_2 = \phi_3 + i\gamma$, a pole in the ϕ_3-plane at $\phi_3 = \phi_4 + i\gamma$, a pole in the ϕ_4-plane at $\phi_4 = \phi_5 + i\gamma$...and a pole in the $\phi_{N-1}-$plane

at $\phi_{N-1} = \phi_N + i\gamma$. By using the residue theorem we get

$$\begin{aligned} Z_\beta &= (-1)^{N-1}\Big[-(-2\pi i)^{N-2}\oint d\phi_1 d\phi_N \delta(\phi_1 + (N-1)\phi_N + \frac{1}{2}(N-1)(N-2)i\gamma) \\ &\times e^{-\frac{N}{g^2}\left(\phi_1^2+(\phi_N+(N-2)i\gamma)^2+...+(\phi_N+i\gamma)^2+\phi_N^2\right)} e^{i\beta\left(\phi_1+(\phi_N+(N-2)i\gamma)+...+(\phi_N+i\gamma)+\phi_N\right)} \\ &\times \frac{1}{\phi_1-\phi_N+i\gamma}\frac{1}{\phi_1-\phi_N-(N-1)i\gamma}\Big]. \end{aligned} \tag{8.58}$$

The integration over ϕ_1 will be dominated by the pole at $\phi_1 = \phi_N + (N-1)i\gamma$. The delta function becomes

$$\begin{aligned} \delta(\phi_1 + (N-1)\phi_N + \frac{1}{2}(N-1)(N-2)i\gamma) &= \delta\Big(N(\phi_N + \frac{1}{2}(N-1)i\gamma)\Big) \\ &= \delta\Big(\frac{N}{2}(\phi_1+\phi_N)\Big). \end{aligned} \tag{8.59}$$

In other words we must have (we take the limit $\beta \longrightarrow 0$)

$$\begin{aligned} Z_\beta &= (-1)^{N-1}\Big[-(-2\pi i)^{N-2}\oint d\phi_1 d\phi_N \delta\Big(\frac{N}{2}(\phi_1+\phi_N)\Big) e^{-\frac{N}{g^2}\left(\phi_1^2+(\phi_N+(N-2))^2+...+(\phi_N+1)^2+\phi_N^2\right)} \\ &\times \frac{1}{\phi_1-\phi_N+1}\frac{1}{\phi_1-\phi_N-(N-1)}\Big] \\ &= (-1)^{N-1}\Big[-(-2\pi i)^{N-1}\oint d\phi_N \frac{1}{N}\delta\Big(\phi_N+\frac{N-1}{2}\Big) e^{-\frac{N}{g^2}\left(\phi_N^2+(\phi_N+(N-2))^2+...+(\phi_N+1)^2+\phi_N^2\right)}\frac{1}{N}\Big] \\ &= (-1)^N(2\pi i)^{N-1}\frac{1}{N^2}\exp\Big(-\frac{N}{g^2}\sum_{m=-\frac{N-1}{2}}^{m=\frac{N-1}{2}} m^2\Big) \\ &= (-1)^N(2\pi i)^{N-1}\frac{1}{N^2}\exp\Big(-\frac{N^2}{3g^2}s(s+1)\Big)\ ,\ s=\frac{N-1}{2}. \end{aligned} \tag{8.60}$$

The smallest eigenvalue is $\phi_N = -(N-1)/2$ and the largest eigenvalue is $\phi_1 = (N-1)/2$. We observe that $\phi_1 = \phi_N + N - 1$. We have in total $N = 2s+1$ eigenvalues between ϕ_N and ϕ_1 with a step equal 1, viz $m = (N-1)/2, (N-3)/2, ..., -(N-3)/2, -(N-1)/2$. This vacuum configuration corresponds precisely to the $SU(2)$ irreducible representation $s = (N-1)/2$. The vacuum energy defined as the logarithm of the partition function is clearly proportional to the quadratic Casimir in the irreducible representation $s = (N-1)/2$. In summary we have found that the partition function is dominated by the integration in the vicinity of the poles $\phi_i - \phi_j + 1 = 0$ which corresponds to the irreducible representation of $SU(2)$ of size N.

8.3 Saddle-Point Method: The Matrix Phase

Hermitian Case: We will keep assuming that the matrix ϕ is hermitian. The effective potential derived from the path integral (8.46) is given by

$$-V_{\text{eff}}(\phi_i) = -Nt\sum_i \phi_i^2 + \frac{1}{2}\sum_{i\neq j}\ln(\phi_i-\phi_j)^2 - \frac{1}{2}\sum_{i\neq j}\ln\Big(-t(\phi_i-\phi_j)^2+t\Big). \tag{8.61}$$

The saddle point associated with this potential is essentially the inverted oscillator problem which is the analytic continuation of the supersymmetric model considered in [32]. More importantly the observation that the saddle point associated with this potential actually also corresponds to the Baxter's three-colorings problem [69].

As before we will define $t = 1/g^2$. The saddle-point equation reads explicitly

$$\frac{2}{g^2}\phi_k = \frac{2}{N}\sum_{i\neq k}\frac{1}{\phi_k-\phi_i} - \frac{1}{N}\sum_{j\neq k}\left[\frac{1}{1+\phi_k+\phi_j} - \frac{1}{1-\phi_k-\phi_j}\right]. \tag{8.62}$$

We introduce the density of eigenvalues and the resolvent given by

$$\rho(x) = \frac{1}{N}\sum_i \delta(x-\phi_i)\ ,\ W(z) = \int dx \frac{\rho(x)}{z-x}. \tag{8.63}$$

The saddle-point equation becomes

$$\frac{2}{g^2}z = 2\int dy \frac{\rho(y)}{z-y} - \int dy\left[\frac{\rho(y)}{1+z-y} - \frac{\rho(y)}{1-z+y}\right]. \tag{8.64}$$

In terms of the resolvent this reads

$$\frac{2}{g^2}z = W(z+i\epsilon) + W(z-i\epsilon) + W(-1-z) + W(1-z). \tag{8.65}$$

We observe that the term $\sum_j 1/(1-\phi_k-\phi_j)$ is singular if one of the eigenvalues approaches $1/2$ whereas the term $\sum_j 1/(1+\phi_k+\phi_j)$ is singular if one of the eigenvalues approaches $-1/2$. We are interested in the case where the eigenvalues live on a single interval $[a,b] \subset [-1/2, 1/2]$. Thus $W(z)$ is analytic everywhere in the complex plane except along the cut $[a,b]$. The above equation can be rewritten as

$$W(z+i\epsilon) = \frac{2}{g^2}z - W(z-i\epsilon) - W(-1-z) - W(1-z)\ ,\ z\in[a,b]. \tag{8.66}$$

Thus as the complex number z crosses the cut $[a,b]$ from the first sheet into the second sheet we see that the resolvent $W(z)$ becomes a linear combination of $W(z)$, $W(1-z)$ and $W(-1-z)$. In other words we have three cuts $[a,b]$, $[1-b,1-a]$ and $[-1-b,-1-a]$ in the second sheet. By crossing the cuts $[a,b]$, $[1-b,1-a]$ and $[-1-b,-1-a]$ into the third sheet we generate more cuts. Hence the domain of definition of $W(z)$ is a Riemann surface of infinite genus with an infinite number of cuts in each sheet.

By comparison the one-matrix model (we set $2z/g^2$ to $V^{'}(z)/g^2$ and $W(-1-z)+W(1-z)$ to 0) yields a Riemann surface with one cut in each of the two possible sheets whereas the $O(n)$-matrix model (we set $2z/g^2$ to $V^{'}(z)/g^2$ and $W(-1-z)+W(1-z)$ to $nW(-z)$) yields a Riemann surface with two cuts in each of the two possible sheets.

We introduce now the notation $z_k = (-1)^k(z-k)$. The saddle-point equation (8.65) is equivalent to the loop equation [67]

$$S(z) = 0. \tag{8.67}$$

$$S(z) = \sum_{k=1}^{+\infty}(f(z_k) + f((1-z)_k)). \tag{8.68}$$

$$f(z) \;=\; W^2(z) + \frac{1}{2}(W(1-z)+W(-1-z))W(z) - \frac{1}{g^2}(2zW(z)-R(z)). \quad (8.69)$$

The function $S(z)$ has no cut throughout the complex plane and it satisfies $S(z+2)=S(z)$, $S(1-z)=S(z)$. In order to guarantee convergence of the sum we have subtracted the polynomial part $R(z_k)$ of $2z_kW(z_k)$.

Next we can easily verify that the resolvent can be rewritten in terms of the moments t_n of the matrix ϕ as

$$W(z) \;=\; \sum_{n=0}^{\infty} \frac{t_n}{z^{n+1}} \;,\; t_n = \int dx x^n \rho(x) = \frac{1}{N} Tr\phi^n. \quad (8.70)$$

After a long calculation we can rewrite the saddle-point equation (8.67) as

$$T_q = \sum_{p=0}^{q-1} T_{q-p-1}T_p + 2g^2 \sum_{p=0}^{\infty}\sum_{m=0}^{\infty} g^{2(p+m)} T_p T_{m+q} C_{2p}^{2(p+m)+1} \;,\; T_q = \frac{t_{2q}}{2g^{2q}}. \quad (8.71)$$

It is not difficult to show now that the free theory $g^2=0$ corresponds to a density of eigenvalues given by the Wigner's semicircle law

$$\rho(x) = \frac{2}{\pi a^2}\sqrt{a^2-x^2} \;,\; a^2 = 2g^2. \quad (8.72)$$

A perturbative solution around this free solution can be constructed following the method of [67]. However the exact solution as we will see shortly is quite different from the prediction of perturbation theory. This result is rather expected since in the limit of interest $\alpha \longrightarrow 0$ we have $t \longrightarrow 0$ and as a consequence $g^2 \longrightarrow \infty$. This conclusion is actually also confirmed By Monte Carlo simulations.

Eigenvalues Distribution: As we have already said the analytic continuation of our model is essentially the model studied in [34]. However the exact solution we would like to construct here is entirely based on the eigenvalues distribution of the matrix ϕ from which we can calculate all observables of interest to us. This explicit solution is rather different from the sophisticated implicit solution found in [34]. The eigenvalues distribution we will derive shortly is also different from the one presented in [61] and it agrees well with the numerical Monte Carlo simulations.

Let us first recall our notation

$$t = \frac{1}{g^2} = \frac{\alpha^4}{32}. \quad (8.73)$$

Let us next consider the saddle point equation once again. This equation can be rewritten in the form

$$\frac{z}{g^2} = \int dy \frac{\rho(y)}{(z-y)(1-(z-y)^2)} \;,\; \int dy\rho(y) = 1. \quad (8.74)$$

We have

$$\begin{aligned} \frac{z}{g^2} \;&=\; \int_{z-L}^{z+L} dx \frac{\rho(z-x)}{x(1-x^2)} \\ &=\; \rho(z)\int_{z-L}^{z+L} dx \frac{1}{x(1-x^2)} - \rho^{'}(z)\int_{z-L}^{z+L} dx \frac{1}{1-x^2} + \rho^{''}(z)\int_{z-L}^{z+L} dx \frac{x}{2(1-x^2)} + ... \end{aligned} \quad (8.75)$$

We have

$$\int \frac{dx}{x(1-x^2)} = -\frac{1}{2}\Big(-\frac{1}{x^2} - \frac{1}{2x^4} + ...\Big). \tag{8.76}$$

$$\int dx \frac{1}{1-x^2} = \frac{1}{x} + \frac{1}{3x^3} + ... \tag{8.77}$$

$$\int dx \frac{x}{2(1-x^2)} = -\frac{1}{4}\ln(x^2-1). \tag{8.78}$$

We will assume 2 things:

- A quadratic distribution.
- An (infinite) support $[-L, L]$.

We get then to leading contribution in $1/L$ the expansion

$$\frac{z}{g^2} = \rho(z)(-\frac{2z}{L^3} + ...) - \rho^{'}(z)(\frac{2}{L} + ...) + \rho^{''}(z)(-\frac{z}{L} + ...) + ... \tag{8.79}$$

We assume a quadratic distribution which is also symmetric given by

$$\rho(z) = a + bz^2. \tag{8.80}$$

Normalization gives

$$a = \frac{1}{2L} - \frac{bL^2}{3}. \tag{8.81}$$

The saddle-point equation to leading order in $1/L$ becomes

$$\frac{z}{g^2} = -\frac{6bz}{L} + ... \tag{8.82}$$

In other words

$$b = -\frac{1}{g^2}\frac{L}{6}. \tag{8.83}$$

The distribution becomes

$$\begin{aligned} \rho(z) &= \frac{1}{2L} + \frac{L^3}{18g^2} - \frac{L}{6g^2}z^2 \\ &= \frac{L}{6g^2}(L^2 - z^2) \\ &= \frac{3}{4L^3}(L^2 - z^2). \end{aligned} \tag{8.84}$$

We imposed the condition

$$\frac{1}{2L} + \frac{L^3}{18g^2} = \frac{L^3}{6g^2} \Leftrightarrow L = (\frac{9}{2})^{\frac{1}{4}}\sqrt{g}. \tag{8.85}$$

By performing the rescaling $z \longrightarrow z_0 = (L_0/L)z$ we can bring the above distribution to the form

$$\rho_0(z_0) \quad = \quad \frac{3}{4L_0^3}(L_0^2 - z_0^2). \tag{8.86}$$

This can be derived from the same saddle-point equation (8.74) and therefore the same path integral (8.46) with a coupling constant $t_0 = 1/g_0^2$ where g_0 is defined by the equation

$$L_0 = (\frac{9}{2})^{\frac{1}{4}}\sqrt{g_0}. \tag{8.87}$$

The original normalization of the matrices corresponds to $L_0/L = \alpha\phi$. Thus we have

$$\begin{aligned} L_0 &= \alpha\phi L \\ &= 2\sqrt{3}\phi \\ &= \sqrt{3}(1 + \sqrt{1 - 4\tilde{\beta}}). \end{aligned} \tag{8.88}$$

This is independent of N and α which is precisely what we observe in Monte Carlo simulations. For the value of $\tilde{\beta}$ at hand which for $\tilde{\zeta_0} = -1/24$ is $\tilde{\beta} = 1/4$ we get the prediction $L_0 = \sqrt{3}$. If we simply apply this formula for $\tilde{\beta} = 2/9$ we obtain the prediction $L_0 = 4/\sqrt{3} = 2.31$ which should be compared with the measured value $L_0 = 2.85$.

Since the above distribution will work only for large L it must only be valid for large g^2 which is equivalent to small α. This is the regime of the matrix phase. We must have then

$$L >> 1 \Leftrightarrow g^2 >> \frac{2}{9}. \tag{8.89}$$

In other words we must have the following lower estimate of the critical value

$$\alpha << \alpha_* = 2\sqrt{3}. \tag{8.90}$$

Antihermitian Case: The above distribution is the same distribution which was found for large values of g^2 for the antihermitian model in [61]. However the crucial difference is the functional dependence of L on g which we will now briefly discuss.

To get the model of [34] and [61] we must assume that ϕ is antihermitian and take $\kappa_1 - 2\epsilon > 0$ and $\kappa_1 < 0$, i.e. $\zeta_0 > 0$. We get the path integral

$$Z = \int d\phi \; dX_1 \; dX_2 \exp Nt\Big(- 2iTr\phi[X_1, X_2] + Tr\phi^2 - TrX_i^2\Big). \tag{8.91}$$

In this case

$$t \quad = \quad -\frac{\alpha^4}{32}. \tag{8.92}$$

Integration over X_1 and X_2 yields

$$Z \quad = \quad \int \prod_{i=1}^{N} d\phi_i \prod_{i<j}(\phi_i - \phi_j)^2 \prod_{i<j}\Big(- Nt(\phi_i - \phi_j)^2 + Nt\Big)^{-1} \exp\Big(Nt\sum_i \phi_i^2\Big). \tag{8.93}$$

We get the effective potential (shifting the eigenvalues as $\phi_i \longrightarrow i\phi_i$)

$$-V_{\rm eff}(\phi_i) = -Nt\sum_i \phi_i^2 + \frac{1}{2}\sum_{i\neq j}\ln(\phi_i-\phi_j)^2 - \frac{1}{2}\sum_{i\neq j}\ln\Big(t(\phi_i-\phi_j)^2+t\Big). \quad (8.94)$$

The saddle-point equation is

$$\frac{1}{g^2}\phi_k = \frac{1}{N}\sum_{i\neq k}\frac{1}{(\phi_k-\phi_i)\big(1+(\phi_k-\phi_i)^2\big)}. \quad (8.95)$$

Therefore in this case the saddle-point equation is given by

$$\frac{z}{g^2} = \int dy \frac{\rho(y)}{(z-y)(1+(z-y)^2)}. \quad (8.96)$$

We go now through the same steps. We have

$$\begin{aligned}\frac{z}{g^2} &= \int_{z-L}^{z+L} dx \frac{\rho(z-x)}{x(1+x^2)} \\ &= \rho(z)\int_{z-L}^{z+L} dx \frac{1}{x(1+x^2)} - \rho^{'}(z)\int_{z-L}^{z+L} dx \frac{1}{1+x^2} + \rho^{"}(z)\int_{z-L}^{z+L} dx \frac{x}{2(1+x^2)} + ... \\ &= -\frac{1}{2}\rho(z)\ln(1+\frac{1}{x^2})|_{z-L}^{z+L} - \rho^{'}(z)\arctan x|_{z-L}^{z+L} + \frac{1}{4}\rho^{"}(z)\ln(1+x^2)|_{z-L}^{z+L} + ...\end{aligned} \quad (8.97)$$

Again we assume a symmetric quadratic distribution. As before only the above three terms will contribute. The first term is still of order $1/L^3$, the third term is still of order $1/L$ whereas the second term becomes of order 1. The saddle-point equation to leading order in $1/L$ becomes

$$\frac{z}{g^2} = -\pi\rho^{'}(z) + ... \quad (8.98)$$

We immediately obtain

$$\rho(z) = -\frac{z^2}{2\pi g^2} + a. \quad (8.99)$$

Normalization gives

$$a = \frac{1}{2L} + \frac{L^2}{6\pi g^2}. \quad (8.100)$$

We obtain the distribution

$$\begin{aligned}\rho(z) &= \frac{1}{2\pi g^2}(2\pi g^2 a - z^2) \\ &= \frac{3}{4L^3}(L^2-z^2).\end{aligned} \quad (8.101)$$

We imposed the condition

$$L^2 = 2\pi g^2 a \Leftrightarrow L = (\frac{3\pi}{2})^{\frac{1}{3}} g^{\frac{2}{3}}. \quad (8.102)$$

By comparing with the numerical results we will find that the hermitian prediction is more accurate than this antihermitian calculation.

9 Summary and Future Directions

In this article we employed supersymmetry, cohomological deformation, localization and the saddle-point method as well as the Monte Carlo method to study nonperturbatively Yang-Mills matrix models in $D = 4$ with mass terms. We can summarize the main results, findings and conjectures of this work as follows:

- By imposing the requirement of supersymmetry and $SO(3)$ covariance we have shown that there exists a single mass deformed Yang-Mills quantum mechanics in $D = 4$ which preserves all four real supersymmetries of the original theory although in a deformed form. This is the 4 dimensional analogue of the 10 dimensional BMN model. Full reduction yields a unique mass deformed $D = 4$ Yang-Mills matrix model. This latter 4 dimensional model is the analogue of the 10 dimensional IKKT model.
- By using cohomological deformation of supersymmetry we constructed a one-parameter (ζ_0) family of cohomologically deformed $D = 4$ Yang-Mills matrix models which preserve two supercharges. The mass deformed model is one limit ($\zeta_0 \longrightarrow 0$) of this one-parameter family of cohomologically deformed Yang-Mills models.
- We studied the models with the values $\tilde{\beta} = 0$ and $\tilde{\beta} = 2/9$ where $\tilde{\beta}$ is the mass parameter of the bosonic matrices X_a. The second model is special in the sense that classically the configurations $X_a \sim L_a, X_4 = 0$ is degenerate with the configuration $X_a = 0, X_4 = 0$.
- The Monte Carlo simulation of the bosonic $D = 4$ Yang-Mills matrix model with mass terms shows the existence of an exotic first/second order transition from a phase with a well defined background geometry given by the famous fuzzy sphere to a phase with commuting matrices with no geometry in the sense of Connes. The transition looks first order due to the jump in the action whereas it looks second order due to the divergent peak in the specific heat.
- The fuzzy sphere is less stable as we increase the mass term of the bosonic matrices X_a, i.e. as we increase $\tilde{\beta}$. For $\tilde{\beta} = 2/9$ we find the critical value $\tilde{\alpha}_* = 4.9$ whereas for $\tilde{\beta} = 0$ we find the critical value $\tilde{\beta} = 2.55$.
- The measured critical line in the plane $\tilde{\alpha} - \tilde{\beta}$ agrees well with the theoretical prediction coming from the effective potential calculation.
- The order parameter of the transition is given by the inverse radius of the sphere defined by $1/r = TrX_a^2/(\tilde{\alpha}^2 c_2)$. The radius is equal to $1/\phi^2$ (where ϕ is the classical configuration) in the fuzzy sphere phase. At the transition point the sphere expands abruptly to infinite size. Then as we decrease the inverse temperature (the inverse gauge coupling constant) $\tilde{\alpha}$, the size of the sphere shrinks fast to 0, i.e. the sphere evaporates.
- The fermion determinant is positive definite for all gauge configurations in $D = 4$. We have conjectured that the path integral is convergent as long as the scalar curvature (the mass of the fermionic matrices) is zero.

- We have simulated the two models $\tilde{\beta} = 0$ and $\tilde{\beta} = 2/9$ with dynamical fermions. The model with $\tilde{\beta} = 0$ has two supercharges while the model $\tilde{\beta} = 2/9$ has a softly broken supersymmetry since in this case we needed to set by hand the scalar curvature to zero in order to regularize the path integral.

  Thus $\tilde{\beta} = 0$ is amongst the very few models (which we known of) with exact supersymmetry which can be probed and accessed with the Monte Carlo method.

- The fuzzy sphere is stable for the supersymmetric $D = 4$ Yang-Mills matrix model with mass terms in the sense that the bosonic phase transition is turned into a very slow crossover transition. The transition point $\tilde{\alpha}$ is found to scale to zero with N. There is no jump in the action nor a peak in the specific heat.

- The fuzzy sphere is stable also in the sense that the radius is equal $1/\phi^2$ over a much larger region then it starts to decrease slowly as we decrease the inverse temperature $\tilde{\alpha}$ until it reaches 0 at $\tilde{\alpha} = 0$. We claim that the value where the radius starts decreasing becomes smaller as we increase N.

  The model at $\tilde{\alpha} = 0$ can never sustain the geometry of the fuzzy sphere since it is the non deformed model so in some sense the transition to commuting matrices always occurs and in the limit $N \longrightarrow \infty$ it will occur at $\tilde{\alpha}_* \longrightarrow 0$.

- We have spent a lot of time in trying to determine the eigenvalues distributions of the matrices X_μ in both the bosonic and supersymmetric theories. A universal behavior seems to emerge with many subtleties. These can be summarized as follows:

  - In the fuzzy sphere the matrices X_a are given by the $SU(2)$ irreducible representations L_a. For example diagonalizing the matrix X_3 gives N eigenvalues between $(N-1)/2$ and $-(N-1)/2$ with a step equal 1, viz $m = (N-1)/2, (N-3)/2, ..., -(N-3)/2, -(N-1)/2$.
  - In the matrix phase the matrices X_μ become commuting. More explicitly the eigenvalues distribution of any of the matrices X_μ in the matrix phase is given by the non-polynomial law

$$\rho_4(x) = \frac{8}{3\pi R^4}(R^2 - x^2)^{\frac{3}{2}}. \tag{9.1}$$

    This can be obtained from the conjecture that the joint probability distribution of the four matrices X_μ is uniform inside a solid ball with radius R.
  - In the matrix phase the eigenvalues distribution of any of the X_a, say X_3, is given by the above non-polynomial law with a radius R independent of $\tilde{\alpha}$ and N.
  - This is also confirmed by computing the radius in this distribution and comparing to the Monte Carlo data.
  - A very precise measurement of the transition point can be made by observing the point at which the eigenvalues distribution of X_3 undergoes the transition from the N-cut distribution to the above non-polynomial law.
  - The eigenvalues distribution of X_4 is always given by the above non-polynomial law, i.e. for all values of $\tilde{\alpha}$, with a radius R which depends on $\tilde{\alpha}$ and N.

- Another signal that the matrix phase is fully reached is when the eigenvalues distribution of X_4 coincides with that of X_3. From this point downward the eigenvalues distribution of X_4 ceases to depend on $\tilde{\alpha}$ and N.
- Monte Carlo measurements seems to indicate that $R = 1.8$ for bosonic models and $R = 2.8$ for supersymmetric models. The distribution becomes wider in the supersymmetric case.
- We have also observed that the eigenvalues of the normal scalar field $X_a^2 - c_2$ in the fuzzy sphere are also distributed according to the above non-polynomial law. This led us to the conjecture that the eigenvalues of the gauge field on the background geometry are also distributed according to the above non-polynomial law. Recall that the normal scalar field is the normal component of the gauge field to the background geometry which is the sphere here.

- In the $D = 3$ Yang-Mills matrix model with mass terms the eigenvalues distribution becomes polyonomial (parabolic) given by

$$\rho_3(x) = \frac{3}{4R^3}(R^2 - x^2). \tag{9.2}$$

  It was difficult for us in this article to differentiate with certainty between the two distributions ρ_4 and ρ_3 in the three dimensional setting.

- We have also attempted to compute the above eigenvalues distributions analytically. Using localization techniques we were able to find a special set of parameters for which the $D = 4$ Yang-Mills matrix model with mass terms can be reduced to the three dimensional Chern-Simons (CS) matrix model. The saddle-point method leads then immediately to the eigenvalues distributions ρ_3. We believe that our theoretical prediction for the value of R is reasonable compared to the Monte Carlo value.
- We have also made a preliminary comparison between the dependence of R on α in the hermitian and antihermitian CS matrix models. The hermitian case seems more appropriate for the description of the eigenvalues of X_3 whereas the antihermitian case may be relevant to the description of the eigenvalues of X_4.
- Finally, we conjecture that the transition from a background geometry to the phase of commuting matrices is associated with spontaneous supersymmetry breaking. Indeed mass deformed supersymmetry preserves the fuzzy sphere configuration but not diagonal matrices.

Among the future directions that can be considered we will simply mention the following four points:

- Higher precision Monte Carlo simulations of the models studied in this article is the first obvious direction for future investigation. The most urgent question (in our view) is the precise determination of the behavior of the eigenvalues distributions in $D = 4$ and $D = 3$. An analytical derivation of ρ_3 and especially ρ_4 is an outstanding problem.
- Finding matrix models with emergent 4 dimensional background geometry is also an outstanding problem.

- Models for emergent time, and to a lesser extent emergent gravity, and as a consequence emergent cosmology are very rare.
- Monte Carlo simulation of supersymmetry based on matrix models seems to be a very promising goal.

A Algorithms and Simulations

We will use the Metropolis algorithm to compute the probability distribution

$$d\mathcal{P}(X_\mu) = \frac{1}{Z}\delta\left(TrX_\mu\right) \det\mathcal{D}\; e^{-S_B}. \tag{A.1}$$

In problems involving fermions and/or matrices, the Hybrid Monte Carlo algorithm would have been a better choice as it involves global updates as opposed to local updates involved in the Metropolis and as a consequence it is more efficient for non local theories. The disadvantage in using the Hybrid Monte Carlo algorithm is the fact that the molecular dynamics part of this algorithm contains two parameters (the time step size and the number of molecular dynamics steps) which require optimization while the Metropolis algorithm is free from extraneous parameters. Since we will be reporting data with the fermion determinant for small values of N up to $N = 10$ we prefer here the Metropolis algorithm over the Hybrid Monte Carlo algorithm. For the bosonic theory the Metropolis algorithm is quite efficient and we can reach up to $N = 100$ as in [55, 56]. The data with the fermion determinant for large values of N using the Hybrid Monte Carlo algorithm will be reported elsewhere [203].

We have used two random numbers in these simulations: RAN2 and RANLUX. We have found no discernible or measurable differences between these two generators. For consistency, the data reported here is all with RAN2. The errors were estimated using the jackknife method which is supposed to take into account and suppress statistical correlations. The determinant of the Dirac operator and the eigenvalues are computed using LAPACK.

A simulation consists of $T_{\rm th} + T_{\rm mc}$ sweeps where $T_{\rm th}$ is the number of thermalization sweeps and $T_{\rm mc}$ is the number of Monte Carlo sweeps. For all simulations with the fermion determinant we choose $T_{\rm th} = T_{\rm mc} = 2^{13}$. For the bosonic simulations we choose $T_{\rm th} = T_{\rm mc} = 2^{13} - 2^{18}$. We have checked that there is no difference between starting from a cold start and a hot start in bosonic simulations with $\tilde{\beta} = 0$. The same holds for bosonic simulations with $\tilde{\beta} \neq 0$ although thermalization becomes somehow difficult. For the supersymmetric models we always start from the matrices $X_4 = 0$, $X_a = \phi L_a$ since thermalization is very costly in this case.

In a Monte Carlo sweep we update every single entry of the four matrices X_μ once and thus a Monte Carlo sweep contains $2(N^2 + N)$ Metropolis steps. This consists one unit of time or a step of the Monte Carlo evolution.

In the actual code there was no symmetry between the matrix X_4 and the matrices X_a in the sense that we chose different intervals from which we pick the variations of X_4

and X_a. These intervals are adjusted at each Monte Carlo unit of time (sweep) so that the acceptance rates for X_4 and X_a are fixed separately between 25 and 30 per cent.

In actual numerical simulations it is of vital importance to remove the free degrees of freedom TrX_μ, $Tr\theta_\alpha$ and $Tr\theta_\alpha^+$ in order to achieve a very efficient code. After updating the diagonal matrix element i of a given matrix X_μ as: $(X_\mu)_{ii} \longrightarrow (X_\mu)_{ii} = (X_\mu)_{ii} + d + d^*$ the trace changes as: $TrX_\mu = 0 \longrightarrow TrX_\mu = d + d^*$. Thus to restore a traceless matrix X_μ we subtract from it the matrix $-(d+d^*)\mathbf{1}_N/N$ and as a consequence we change the diagonal entries of X_μ as

$$\begin{aligned}(X_\mu)_{ii} &\longrightarrow (X_\mu)_{ii} = (X_\mu)_{ii} + d + d^* - \frac{d+d^*}{N} \\ (X_\mu)_{jj} &\longrightarrow (X_\mu)_{jj} = (X_\mu)_{jj} - \frac{d+d^*}{N}\ ,\ j \neq i. \end{aligned} \tag{A.2}$$

We found that this is the only prescription of imposing tracelessness that works in the matrix phase. The effect of the tracelessness condition on the determinant of the Dirac operator is discussed in the next appendix.

B The Dirac Operator in Simulations

The aim is to simulate the action

$$S = S_B - \frac{1}{N\alpha} Tr\theta^+ \Big(i[X_4, ..] + \sigma_a [X_a, ..] + \alpha\tilde{\xi} \Big)\theta. \tag{B.1}$$

$$S_B = NTr\Big[-\frac{1}{4}[X_\mu, X_\nu]^2 + \frac{2i\alpha}{3}\epsilon_{abc} X_a X_b X_c \Big] + N\tilde{\beta}\alpha^2 TrX_a^2. \tag{B.2}$$

We work with the effective action

$$S_{\text{eff}} = S_B - Tr_{\text{ad}} \log \mathcal{D}. \tag{B.3}$$

The Dirac operator is given by

$$\mathcal{D} = iX_4 - iX_4^R + \sigma_a X_a - \sigma_a X_a^R + \alpha\tilde{\xi}. \tag{B.4}$$

It is possible to rewrite the Dirac action in the following form (with $X_{34} = X_3 + iX_4$)

$$\begin{aligned} Tr\theta^+\mathcal{D}\theta &= Tr\Big[\theta_1^+(X_{34} + \alpha\tilde{\xi})\theta_1 + \theta_1^+ X_- \theta_2 + \theta_2^+ X_+ \theta_1 + \theta_2^+(-X_{34}^+ + \alpha\tilde{\xi})\theta_2\Big] \\ &- Tr\Big[X_{34}\theta_1^+\theta_1 + X_-\theta_1^+\theta_2 + X_+\theta_2^+\theta_1 - X_{34}^+\theta_2^+\theta_2\Big]. \end{aligned} \tag{B.5}$$

Following [46,47], we expand the $N \times N$ matrices θ_1, θ_2 and θ_1^+, θ_2^+ as $\theta_i = \sum_{A=1}^{N^2} \theta_i^A T^A$ and $\theta_i^+ = \sum_{A=1}^{N^2} (\theta_i^A)^* (T^A)^+$ where the $N \times N$ matrices T^A are defined by $(T^A)_{ij} = \delta_{ii_A}\delta_{jj_A}$

with i_A and j_A are such that $A = N(i_A - 1) + j_A$ whereas the matrices $(T^A)^+$ are defined by $(T^A)^+_{ij} = \delta_{ii_A}\delta_{jj_A}$ with i_A and j_A such that $A = N(j_A - 1) + i_A$. Then we find that

$$Tr\theta^+\mathcal{D}\theta = \chi_1^*\mathcal{M}_{11}\chi_1 + \chi_1^*\mathcal{M}_{12}\chi_2 + \chi_2^*\mathcal{M}_{21}\chi_2 + \chi_2^*\mathcal{M}_{22}\chi_2. \tag{B.6}$$

The matrices $\mathcal{M}_{ij}$ are $N^2 \times N^2$ defined by

$$\begin{aligned}
(\mathcal{M}_{11})^{AB} &= Tr(T^A)^+(X_{34} + \alpha\tilde{\xi})T^B - TrX_{34}(T^A)^+T^B \\
(\mathcal{M}_{12})^{AB} &= Tr(T^A)^+X_-T^B - TrX_-(T^A)^+T^B \\
(\mathcal{M}_{21})^{AB} &= Tr(T^A)^+X_+T^B - TrX_+(T^A)^+T^B \\
(\mathcal{M}_{22})^{AB} &= Tr(T^A)^+(-X_{34}^+ + \alpha\tilde{\xi})T^B + TrX_{34}^+(T^A)^+T^B.
\end{aligned} \tag{B.7}$$

We remark that

$$\begin{aligned}
&Tr(T^A)^+XT^B - TrX(T^A)^+T^B = X_{j_Aj_B}\delta_{i_Bi_A} - X_{i_Bi_A}\delta_{j_Aj_B} \\
&Tr(T^A)^+T^B = \delta_{j_Aj_B}\delta_{i_Bi_A} \\
&A = N(j_A - 1) + i_A \ , \ B = N(j_B - 1) + i_B.
\end{aligned} \tag{B.8}$$

The N^2-dimensional vectors χ_1, χ_2 and χ_1^+, χ_2^+ are defined by $(\chi_i)_A = \theta_i^A$ and $(\chi_i^+)_A = (\theta_i^A)^*$. Thus in terms of the $2N^2-$dimensional vectors χ and χ^+ the above Dirac term becomes

$$Tr\theta^+\mathcal{D}\theta = \chi^+\mathcal{M}\chi. \tag{B.9}$$

We observe that the trace parts of the matrices X_μ drop from the partition function since they correspond to Gaussian distributions. Thus the measure should read $\int dX_\mu \delta(TrX_\mu)$ instead of simply $\int dX_\mu$. Similarly we observe that if we write $\theta = \theta_0 + \eta\mathbf{1}$ then the trace part η will decouple from the rest, viz

$$Tr\theta^+\Big(i[X_4,..] + \sigma_a[X_a,..] + \alpha\tilde{\xi}\Big)\theta = Tr\theta_0^+\Big(i[X_4,..] + \sigma_a[X_a,..] + \alpha\tilde{\xi}\Big)\theta_0 + \alpha\tilde{\xi}\eta^+\eta \tag{B.10}$$

Hence the constant fermion modes η_α can also be integrated out from the partition function and thus we should consider the measure $\int d\theta d\theta^+ \delta(Tr\theta_\alpha)\delta(Tr\theta_\alpha^+)$ instead of $\int d\theta d\theta^+$. We are thus led to consider the partition function

$$Z = \int dX_a \ \delta(TrX_a) \ \det\mathcal{D} \ e^{-S_B}. \tag{B.11}$$

The determinant is given by

$$\begin{aligned}
\det\mathcal{D} &= \int d\theta d\theta^+ \delta(Tr\theta_\alpha)\delta(Tr\theta_\alpha^+) e^{\frac{1}{N\alpha}Tr\theta^+\mathcal{D}\theta} \\
&= \int d\chi d\chi^+ \delta\Big(\sum_{A=1}^{N^2}(\chi_\alpha)_A\delta_{i_Aj_A}\Big)\delta\Big(\sum_{A=1}^{N^2}(\chi_\alpha^+)_A\delta_{i_Aj_A}\Big) e^{\frac{1}{N\alpha}\chi^+\mathcal{M}\chi} \\
&= \int d\chi' d\chi'^+ e^{\frac{1}{N\alpha}Tr'\chi'^+\mathcal{M}'\chi'}.
\end{aligned} \tag{B.12}$$

The vectors $\chi_1^{'}$, $\chi_2^{'}$ are $(N^2-1)-$dimensional. The matrix $\mathcal{M}^{'}$ is $2(N^2-1)\times 2(N^2-1)$ dimensional and it is given by

$$\mathcal{M}_{\alpha\beta}^{'A^{'}B^{'}} = \mathcal{M}_{\alpha\beta}^{A^{'}B^{'}} - \mathcal{M}_{\alpha\beta}^{N^2B^{'}}\delta_{i_{A^{'}}j_{A^{'}}} - \mathcal{M}_{\alpha\beta}^{A^{'}N^2}\delta_{i_{B^{'}}j_{B^{'}}} + \mathcal{M}_{\alpha\beta}^{N^2N^2}\delta_{i_{A^{'}}j_{A^{'}}}\delta_{i_{B^{'}}j_{B^{'}}}. \quad \text{(B.13)}$$

We remark that

$$\mathcal{M}_{\alpha\beta}^{N^2N^2} = \alpha\tilde{\xi}\delta_{\alpha\beta}. \quad \text{(B.14)}$$

Thus we must have

$$\det\mathcal{D} = \det^{'}\mathcal{M}^{'}. \quad \text{(B.15)}$$

We prefer to write $\mathcal{D} = \mathcal{D}_0 + \alpha\tilde{\xi}$. The massless Dirac operator $\mathcal{D}_0$ will lead to the $2(N^2-1)\times 2(N^2-1)$ dimensional matrix $\mathcal{M}_0^{'}$ defined by

$$\mathcal{M}_{0,\alpha\beta}^{'A^{'}B^{'}} = \mathcal{M}_{0,\alpha\beta}^{A^{'}B^{'}} - \mathcal{M}_{0,\alpha\beta}^{N^2B^{'}}\delta_{i_{A^{'}}j_{A^{'}}} - \mathcal{M}_{0,\alpha\beta}^{A^{'}N^2}\delta_{i_{B^{'}}j_{B^{'}}}. \quad \text{(B.16)}$$

$$\begin{aligned}
(\mathcal{M}_{0,11})^{AB} &= Tr(T^A)^+X_{34}T^B - TrX_{34}(T^A)^+T^B \\
(\mathcal{M}_{0,12})^{AB} &= Tr(T^A)^+X_{-}T^B - TrX_{-}(T^A)^+T^B \\
(\mathcal{M}_{0,21})^{AB} &= Tr(T^A)^+X_{+}T^B - TrX_{+}(T^A)^+T^B \\
(\mathcal{M}_{0,22})^{AB} &= -Tr(T^A)^+X_{34}^+T^B + TrX_{34}^+(T^A)^+T^B. \quad \text{(B.17)}
\end{aligned}$$

The $2N^2\times 2N^2$ dimensional identity matrix $\alpha\tilde{\xi}\mathbf{1}_{2N^2}$ will lead to the $2(N^2-1)\times 2(N^2-1)$ dimensional matrix $\alpha\tilde{\xi}(1_{2(N^2-1)}+\gamma)$. This can be calculated as follows. We have

$$\alpha\tilde{\xi}Tr\theta^+\theta = \alpha\tilde{\xi}\sum_{A=1}^{N^2}(\theta_\alpha^A)^*\theta_\alpha^A. \quad \text{(B.18)}$$

We use $\theta_\alpha^{N^2} = -\sum_{A=1}^{N^2-1}\theta_\alpha^A\delta_{i_Aj_A}$ where $A=(i_A-1)N+j_A$. We get

$$\begin{aligned}
\alpha\tilde{\xi}Tr\theta^+\theta &= \alpha\tilde{\xi}\sum_{A=1}^{N^2-1}\sum_{B=1}^{N^2-1}(\theta_\alpha^B)^*\Big(\delta_{AB}+\delta_{i_Aj_A}\delta_{i_Bj_B}\Big)\theta_\alpha^A \\
&= \alpha\tilde{\xi}\sum_{A=1}^{N^2-1}\sum_{B=1}^{N^2-1}(\theta_\alpha^B)^*\Big(\delta_{i_Ai_B}\delta_{j_Aj_B}+\delta_{i_Aj_A}\delta_{i_Bj_B}\Big)\theta_\alpha^A. \quad \text{(B.19)}
\end{aligned}$$

The first term corresponds precisely to the $2(N^2-1)\times 2(N^2-1)$ dimensional identity matrix whereas the second term defines the matrix γ. Hence we can write

$$\det\mathcal{D} = \det^{'}(\mathcal{M}_0^{'}+\alpha\tilde{\xi}+\alpha\tilde{\xi}\gamma). \quad \text{(B.20)}$$

C Calculation of the Mass Deformation

The mass deformed Lagrangian density is

$$\mathcal{L}_\mu = \mathcal{L}_0 + \frac{\mu}{g^2}\mathcal{L}_1 + \frac{\mu^2}{g^2}\mathcal{L}_2. \tag{C.1}$$

$$\mathcal{L}_1 = \mathcal{L}_\psi + \mathcal{L}_{\text{myers}}. \tag{C.2}$$

$$\mathcal{L}_\psi = Tr\bar{\psi}\bigg(ia\mathbf{1}_4 + \frac{1}{2}H_{ij}\gamma^0[\gamma^i,\gamma^j] + c\gamma^1\gamma^2\gamma^3\bigg)\psi. \tag{C.3}$$

$$\mathcal{L}_{\text{myers}} = ie\epsilon_{ijk}TrX_iX_jX_k. \tag{C.4}$$

$$\mathcal{L}_2 = Tr\bigg(-\frac{1}{2!}S_{ab}X_aX_b\bigg). \tag{C.5}$$

We will suppose mass deformed supersymmetric transformations, with a time dependent parameter $\epsilon \equiv \epsilon(t)$ which satisfies $\partial_0\epsilon = \mu\Pi\epsilon$, given by

$$\begin{aligned}
\delta_\mu X_0 &= \delta_0 X_0 \\
\delta_\mu X_i &= \delta_0 X_i \\
\delta_\mu \psi &= \delta_0\psi + \mu\Delta\epsilon.
\end{aligned} \tag{C.6}$$

The variation of $\mathcal{L}_0$, the Myers term and the fermionic mass term under the new supersymmetric transformations is

$$\begin{aligned}
\delta_\mu\mathcal{L}_0 &= \frac{\mu}{g^2}Tr\bar{\psi}\gamma^0\bigg(\frac{1}{2}[\gamma^0,\gamma^i]D_0X_i\Pi - \frac{i}{4}[\gamma^i,\gamma^j][X_i,X_j]\Pi - i\gamma^0\gamma^i[X_i,\Delta] - D_0\Delta \\
&- \mu\Delta\Pi\bigg)\epsilon.
\end{aligned} \tag{C.7}$$

$$\frac{\mu}{g^2}\delta_\mu(\mathcal{L}_{\text{myers}}) = \frac{\mu}{g^2}Tr\bar{\psi}\bigg(\frac{3e}{4}[\gamma^i,\gamma^j][X_i,X_j]\gamma^0\gamma_5\bigg)\epsilon. \tag{C.8}$$

$$\frac{\mu}{g^2}\delta_\mu(Tr\bar{\psi}M\psi) = \frac{\mu}{g^2}Tr\bar{\psi}M\bigg(-[\gamma^0,\gamma^i]D_0X_i + \frac{i}{2}[\gamma^i,\gamma^j][X_i,X_j] + 2\mu\Delta\bigg)\epsilon. \tag{C.9}$$

The terms containing the covariant time derivative take the form

$$\frac{\mu}{g^2}Tr\bar{\psi}\gamma^0D_0\bigg(\gamma^0X\Pi - \Delta - 2\hat{M}X\bigg)\epsilon + \frac{\mu}{g^2}Tr\bar{\psi}XD_0\Pi.\epsilon + 2\frac{\mu}{g^2}Tr\bar{\psi}\gamma^0D_0\hat{M}.X\epsilon. \tag{C.10}$$

We have defined $\hat{M} = -\gamma^0M\gamma^0 = ia\mathbf{1}_4 + \frac{1}{2}H_{ij}\gamma^0[\gamma^i,\gamma^j] - c\gamma^1\gamma^2\gamma^3$. Note that Π, M and $\hat{M}$ are Clifford algebra valued. Requiring the second and third terms to vanish means that

Π, M and $\hat{M}$ must be time independent. Requiring the first term to vanish we obtain the constraint

$$\Delta = \gamma^0 X\Pi - 2\hat{M}X. \tag{C.11}$$

The remainder

$$\begin{aligned}\delta_\mu\Big(\mathcal{L}_0 + \frac{\mu}{g^2}Tr\bar{\psi}M\psi + ie\epsilon_{ijk}\frac{\mu}{g^2}TrX_iX_jX_k\Big) &= \\ \frac{\mu}{g^2}Tr\bar{\psi}\Big(-\frac{i}{4}[\gamma^i,\gamma^j][X_i,X_j](3\gamma^0\Pi + 2\hat{M} - 4c\gamma^1\gamma^2\gamma^3 + 3ie\gamma^0\gamma_5) &- \\ \mu\gamma^0\Delta\Pi + 2\mu M\Delta - i\{\gamma^i,[\hat{M},\gamma^j]\}[X_i,X_j]\Big)\epsilon.&\end{aligned} \tag{C.12}$$

We choose

$$\Pi = \frac{2}{3}\gamma^0\hat{M} - \frac{1}{3}(4c+3e)\gamma^0\gamma^1\gamma^2\gamma^3 = \frac{2}{3}\gamma^0(ia\mathbf{1}_4 + \gamma^0 H) - \frac{1}{3}(6c+3e)\gamma^0\gamma^1\gamma^2\gamma^3. \tag{C.13}$$

We get

$$\begin{aligned}\delta_\mu\Big(\mathcal{L}_0 + \frac{\mu}{g^2}Tr\bar{\psi}M\psi + ie\epsilon_{ijk}\frac{\mu}{g^2}TrX_iX_jX_k\Big) &= \frac{\mu}{g^2}Tr\bar{\psi}\Big(-\mu\gamma^0\Delta\Pi + 2\mu M\Delta \\ &- i\{\gamma^i,[\hat{M},\gamma^j]\}[X_i,X_j]\Big)\epsilon.\end{aligned} \tag{C.14}$$

We can verify that $\{\gamma^i,[\hat{M},\gamma^j]\} = 0$. In other words

$$\delta_\mu\Big(\mathcal{L}_0 + \frac{\mu}{g^2}Tr\bar{\psi}M\psi + ie\epsilon_{ijk}\frac{\mu}{g^2}TrX_iX_jX_k\Big) = \frac{\mu}{g^2}Tr\bar{\psi}\Big(-\mu\gamma^0\Delta\Pi + 2\mu M\Delta\Big)\epsilon. \tag{C.15}$$

This must be identified with

$$\delta_\mu\Big(\mathcal{L}_0 + \frac{\mu}{g^2}Tr\bar{\psi}M\psi + ie\epsilon_{ijk}\frac{\mu}{g^2}TrX_iX_jX_k\Big) = -\frac{\mu^2}{g^2}Tr\bar{\psi}\Big(S_{ij}\gamma^i X_j\Big)\epsilon. \tag{C.16}$$

In other words we must have

$$S_{ij}\gamma^i X_j = \gamma^0\Delta\Pi - 2M\Delta. \tag{C.17}$$

The final result is

$$\delta_\mu\Big(\mathcal{L}_0 + \frac{\mu}{g^2}Tr\bar{\psi}M\psi + ie\epsilon_{ijk}\frac{\mu}{g^2}TrX_iX_jX_k - \frac{\mu^2}{g^2}\frac{1}{2!}S_{ij}TrX_iX_j\Big) = 0. \tag{C.18}$$

We compute

$$\Delta = -\frac{2}{3}\gamma^0(XH + 3HX) - \frac{4}{3}(ia + \frac{3e}{4}\gamma^1\gamma^2\gamma^3)X. \tag{C.19}$$

We get after some algebra

$$\begin{aligned} S_{ij}\gamma^i X_j &= \frac{16}{9}\gamma^0(ia+\frac{3e}{4}\gamma^1\gamma^2\gamma^3)(XH+3HX)-\frac{8}{3}HXH-4H^2X-\frac{4}{9}XH^2 \\ &+ \frac{16}{9}\bigg(-a^2+\frac{9}{16}e^2+3ia(c+\frac{3e}{4})\gamma^1\gamma^2\gamma^3\bigg)X. \end{aligned} \tag{C.20}$$

We have $H=\frac{1}{2}H_{ij}[\gamma^i,\gamma^j]=-iH_{ij}\epsilon_{ijk}\gamma^0\gamma_5\gamma^k$, $\frac{i}{2}[\gamma^i,\gamma^j]=\epsilon_{ijk}\gamma^0\gamma_5\gamma_k$ and $\gamma^0\gamma_5=i\gamma^1\gamma^2\gamma^3$. Thus we can compute that HXH, H^2X and XH^2 can only be linear in γ^i, proportional to the cubic product $\gamma^1\gamma^2\gamma^3$ or proportional to the identity. We can also compute that $HX+3HX=4H_{ij}\gamma^iX_j+4H_{ij}\epsilon_{ijk}X_k\gamma^1\gamma^2\gamma^3$. The term linear in γ^0 reads $-\frac{16}{3}\gamma^0eH_{ij}\epsilon_{ijk}X_k$. This must vanish. Hence either $H_{ij}=0$ or $e=0$. But since we are interested in a non-zero Myers term we take $H_{ij}=0$. We get then

$$S_{ij}\gamma^iX_j = \frac{16}{9}\bigg(-a^2+\frac{9}{16}e^2+3ia(c+\frac{3e}{4})\gamma^1\gamma^2\gamma^3\bigg)X. \tag{C.21}$$

The cubic product must also vanish thus we get

$$c=-\frac{3e}{4}. \tag{C.22}$$

In other words we must have

$$S_{ij}=(e^2-\frac{16}{9}a^2)\delta_{ij}. \tag{C.23}$$

D Star Products on S^2_N And R^2_θ and The Flattening Limit

In this appendix we will show how does the star product on the fuzzy sphere approach the star product on the Moyal-Weyl plane in the flattening limit. We will follow [196].

The commutation relations on the sphere read

$$[x_a,x_b]=\frac{iR}{\sqrt{c_2}}\epsilon_{abc}x_c. \tag{D.1}$$

We define the stereographic projections A and A^+ in terms of the operators x_a as follows

$$A=\frac{1}{2}(x_1-ix_2)B\ ,\ A^+=\frac{1}{2}B(x_1+ix_2)\ ,\ B=\frac{2}{R-x_3}. \tag{D.2}$$

The commutation relation $[x_1,x_2]=iRx_3/\sqrt{c_2}$ takes now the simpler form

$$[A,A^+]=F(|A|^2)\ ,\ F(|A|^2)=\alpha B\bigg[1+|A|^2-\frac{\alpha B}{4}|A|^2-\frac{RB}{2}\bigg]\ ,\ \alpha=\frac{\theta^2}{R}\ ,\ |A|^2=AA^+. \tag{D.3}$$

The constraint $\sum_a x_a^2=R^2$ reads in terms of the new variables

$$\frac{\alpha}{4}\beta B^2-(\beta+\frac{\alpha}{2})B+1+|A|^2=0\ ,\ \beta=R+\alpha|A|^2. \tag{D.4}$$

This quadratic equation can be solved and one finds the solution

$$B{\equiv}B(|A|^2) = \frac{2}{\alpha} + \frac{1}{R+\alpha|A|^2}\Big[1 - \sqrt{1+\frac{4R^2}{\alpha^2}+\frac{4R}{\alpha}|A|^2}\Big]. \tag{D.5}$$

For large N we have $\frac{1}{\beta} = \frac{1}{R}[1-\alpha\frac{|A|^2}{R}]+O(\alpha^2)$ and hence $\frac{\alpha}{2}B = \frac{\alpha}{2R}(1+|A|^2)$ or equivalently $[A,A^+] = \frac{1}{2\sqrt{c_2}}(1+|A|^2)^2+O(\alpha^2)$. From the formula $|A|^2 = L_-(\sqrt{c_2}-L_3)^{-2}L_+$ it is easy to find the spectrum of the operator $F(|A|^2)$. This is given by

$$F(|A|^2)|s,m>= F(\lambda_{s,m})|s,m>\ ,\ s=\frac{N-1}{2}. \tag{D.6}$$

$$\lambda_{s,m} = \frac{c_2-m(m+1)}{(\sqrt{c_2}-m-1)^2} = \frac{n(N-n)}{(\sqrt{c_2}+s-n)^2} = \lambda_{n-1}\ ,\ m=-s,...,+s\ ,\ n=s+m+1=1,...,N. \tag{D.7}$$

Now we introduce ordinary creation and annihilation operators a and a^+ which are defined as usual by $[a,a^+]=1$ with the canonical basis $|n>$ of the number operator $\mathcal{N}=a^+a$, i.e. $\mathcal{N}|n>= n|n>$, $n=0,1,...$, and which also satisfy $a|n>=\sqrt{n}|n-1>$ and $a^+|n>=\sqrt{n+1}|n+1>$. Next we embed the $N-$dimensional Hilbert space H_N generated by the eigenstates $|s,m>$ into the infinite dimensional Hilbert space generated by the eigenstates $|n>$ and then define the maps on H_N given by

$$A = f_N(\mathcal{N}+1)a\ ,\ A^+ = a^+f_N(\mathcal{N}+1). \tag{D.8}$$

It is an identity easy to check that $(\mathcal{N}+1)f_N^2(\mathcal{N}+1)=|A|^2$ and hence $(\mathcal{N}+1)f_N^2(\mathcal{N}+1)|n-1>= nf_N^2(n)|n-1>$ and $|A|^2|s,m>=\lambda_{n-1}|s,m>$. In other words we can identify the first N states $|n>$ in the infinite dimensional Hilbert space of the harmonic oscillator with the states of H_N via

$$|s,m>\leftrightarrow|n-1=s+m>\ . \tag{D.9}$$

As a consequence we have the result $f_N(n)=\sqrt{\frac{\lambda_{n-1}}{n}}$ which clealry indicates that the above map is well define (as it should be) only for states $n{\leq}N$. For example $A|0>= f_L(N+1)a|0>=0$ because $a|0>=0$ but also because $A|0>=\frac{1}{2}(x_1-ix_2)B(|A|^2)|s,-s>= B(\lambda_{s,-s})\frac{R}{2\sqrt{c_2}}L_-|s,-s>=0$. The above map also vanishes identically on $|s,s>=|N-1>$ as one might check. The relation between F and f_N is easily found to be given by

$$F(\lambda_n) = (1+n)f_N^2(n+1)-nf_N^2(n). \tag{D.10}$$

Now we define the corresponding coherent states by

$$|z;N>= \frac{1}{\sqrt{M_N(x)}}\sum_{n=0}^{N-1}\frac{z^n}{\sqrt{n!}[f_N(n)]!}|n>\ ,\ M_N(x)=\sum_{n=0}^{N-1}\frac{(x)^n}{n!([f_N(n)]!)^2}\ ,\ x=|z|^2$$
$$[f_N(n)]! = f_N(0)f_N(1)...f_N(n-1)f_N(n). \tag{D.11}$$

By construction these states are normalized and they are such that

$$A|z;N>=z|z;N>-\frac{1}{\sqrt{M_N(|z|^2)}}\frac{z^N}{\sqrt{(N-1)!}[f_N(N-1)]!}|N-1>. \tag{D.12}$$

In the large N limit we can check that $M_N(x)\longrightarrow(N-1)(1+x)^{N-2}$ and $\sqrt{(N-1)!}[f_N(N-1)]!\longrightarrow\sqrt{\pi(N-1)}$ and hence $A|z;N>\longrightarrow z|z;N>$ which means that $|z;N>$ becomes exactly an $A-$eigenstate.

As it is the case with standard coherent states the above states $|z;N>$ are not orthonormal since $<z_1;N|z_2;N>=M_N(|z_1|^2)^{-\frac{1}{2}}M_N(|z_2|^2)^{-\frac{1}{2}}M_N(\bar{z}_1z_2)$. Using this result as well as the completeness relation $\int d\mu_N(z,\bar{z})|z;N><z;N|=1$ where $d\mu_N(z,\bar{z})$ is the corresponding measure we can deduce the identity

$$M_N(1)=\int d\mu_N(z,\bar{z})\frac{M_N(z)M_N(\bar{z})}{M_N(|z|^2)}. \tag{D.13}$$

This last equation allows us to determine that the measure $d\mu(z,\bar{z})$ is given by

$$d\mu_N(z,\bar{z})=iM_N(|z|^2)X_N(|z|^2)dz\wedge d\bar{z}=2M_N(|z|^2)X_N(|z|^2)\rho d\rho d\theta. \tag{D.14}$$

The function X_N is defined by

$$\int_0^\infty dx\ x^{s-1}X_N(x)=\frac{\Gamma(s)([f_N(s-1)]!)^2}{2\pi}. \tag{D.15}$$

The solution of this equation was found in [196] and it is given by

$$2\pi X_N(x)=F_1(\gamma+N,\gamma+N;N+1;-x)\ ,\ \gamma=\sqrt{c_2}-\frac{N-1}{2}. \tag{D.16}$$

For large N where $|z|^2<<N$ we can find that the behaviour of the measure $d\mu_N(z,\bar{z})$ coincides with the ordinary measure on $\mathbf{S}^2$, viz

$$d\mu_N(z,\bar{z})\simeq\frac{N-1}{2\pi}\frac{idz\wedge d\bar{z}}{(1+|z|^2)^2}. \tag{D.17}$$

With the help of this coherent state $|z;N>$ we can therefore associate to every operator O a function $O_N(z,\bar{z})$ by setting $<z;N|O|z;N>=O_N(z,\bar{z})$. It is therefore clear that the trace of the operator O is mapped to the inetgral of the function O_N against the measure $d\mu_N(z,\bar{z})$, i.e

$$TrO=\int d\mu_N(z,\bar{z})O_N(z,\bar{z}). \tag{D.18}$$

Given now two such operators O and P their product is associated to the star product of their corresponding functions, namely

$$\begin{aligned}&O_N*P_N(z,\bar{z})\equiv<z;N|OP|z;N>=\int d\mu(\eta,\bar{\eta})O_N(\eta,\bar{z})\frac{M_N(\bar{z}\eta)M_N(\bar{\eta}z)}{M_N(|z|^2)M_N(|\eta|^2)}P_N(z,\bar{\eta})\\&O_N(\eta,\bar{z})=(<z;N|\eta;N>)^{-1}<z;L|O|\eta;L>\ ,\ P_N(z,\bar{\eta})=(<\eta;N|z;N>)^{-1}<\eta;N|P|z;N>.\end{aligned} \tag{D.19}$$

The large N limit of this star product is given by the Berezin star product on the sphere [199], namely

$$O_N * P_N(z,\bar{z}) = \frac{N-1}{2\pi}\int \frac{id\eta\wedge d\bar{\eta}}{(1+|\eta|^2)^2} O_N(\eta,\bar{z})\left[\frac{(1+\bar{z}\eta)(1+\bar{\eta}z)}{(1+|z|^2)(1+|\eta|^2)}\right]^{N-2} P_N(z,\bar{\eta}). \quad \text{(D.20)}$$

Finally we comment on the planar (flattening) limit of the above star product which in fact is the central point of our discussion here. In this limit we have $x_3 = -R$ where the minus sign is due to our definition of the stereographic coordinate B in (D.2). The stereographic coordiantes B, A and A^+ are scaled in this limit as

$$B = \frac{1}{R}\ ,\ A = \frac{1}{2R}\hat{A}\ ,\ \hat{A} = \hat{x}_1 - i\hat{x}_2\ ,\ A^+ = \frac{1}{2R}\hat{A}^+\ ,\ \hat{A}^+ = \hat{x}_1 + i\hat{x}_2\ ,\ \hat{x}_i = x_i. \quad \text{(D.21)}$$

This scaling means in particular that the coordinates z and $\bar{z}$ must scale as $z = \hat{z}/2R$ and $\bar{z} = \bar{\hat{z}}/2R$. Since we already know that $[A, A^+] = \frac{1}{2\sqrt{c_2}}(1+|A|^2)^2$ in the large N limit we can immediately conclude that $[\hat{A}, \hat{A}^+] = 2\theta^2$ in this limit or equivalently $[\hat{x}_1, \hat{x}_2] = -i\theta^2$. Next from the result $M_N(x) \longrightarrow (N-1)(1+x)^{N-2}$ when $N \longrightarrow \infty$ we can conlude that in this large N limit we must have

$$M_N(|z|^2) \longrightarrow N\ e^{\frac{1}{2\theta^2}|\hat{z}|^2}. \quad \text{(D.22)}$$

The measure $d\mu_N(z,\bar{z})$ behaves as

$$d\mu_N(z,\bar{z}) = \frac{i}{4\pi\theta^2} d\hat{z}\wedge d\bar{\hat{z}}. \quad \text{(D.23)}$$

Putting all these results together we obtain the Berezin star product on the plane [199], namely

$$O * P(\hat{z},\bar{\hat{z}}) = \frac{i}{4\pi\theta^2}\int d\hat{\eta}\wedge d\bar{\hat{\eta}} O(\hat{\eta},\bar{\hat{z}})\ e^{-\frac{1}{2\theta^2}(\hat{z}-\hat{\eta})(\bar{\hat{z}}-\bar{\hat{\eta}})} P(\hat{z},\bar{\hat{\eta}}). \quad \text{(D.24)}$$

Lastly it is easy to check that the trace behaves in the limit as follows

$$\frac{R^2}{N} Tr \longrightarrow \frac{i}{8\pi}\int d\hat{z}\wedge\bar{\hat{z}}. \quad \text{(D.25)}$$

Acknowledgment: I would like to thank Denjoe O'Connor for extensive discussions at various stages of this project. I would like also to thank R.Delgadillo-Blando and Adel Bouchareb for their collaboration. The numerical simulations reported in this article were conducted on the clusters of the Dublin Institute for Advanced Studies.
